The following were elected

OFFICERS FOR THE ENSUING YEAR.

President.—Dr. E. W. Row, of Orange, Va.

Vice-Presidents.—Drs. Wm. S. Christian, of Urbanna, George S. Luck, of Roanoke, and L. Ashton, of Falmouth.

Recording Secretary.—Dr. Landon B. Edwards, of Richmond, Va.

Corresponding Secretary.—Dr. J. F. Winn, of Richmond, Va.

Treasurer.—Dr. Richard T. Styll, of Hollins, Roanoke Co., Va.

Committee on Applications for Fellowship at Annual Session, 1889.—Drs. Wm. D. Turner, of Ferguson's Wharf, R. M. Slaughter, of Theological Seminary, I. S. Stone, of Lincoln, Alfred S. Rixey, of Culpepper, and John Clopton, of Williamsburg.

Executive Committee.—Drs. Wm. W. Parker, of Richmond, Hon. Fellow J. Herbert Claiborne, of Petersburg, Jacob Michaux, of Richmond, L. Lankford, of Norfolk, and Hon. Fellow Hunter McGuire, of Richmond. The Recording Secretary and the Treasurer are *ex officio* members.

Committee on Publications.—Drs. C. W. P. Brock, George Ross, and Hugh M. Taylor, each of Richmond, Va. The Recording Secretary and Treasurer are *ex officio* members.

Necrological Committee.—Hon. Fellow Dr. J. Edgar Chancellor, of University of Virginia, Chairman.

To Deliver Annual Address to the Public and Profession, Session 1889.—Dr. Thomas J. Moore, of Richmond, Va.

Subject for General Discussion, Annual Session 1889.—Croupous Pneumonia.

Leader in this Discussion.—Dr. B. L. Winston, of Hanover C. H., Va.

Place of Annual Session 1889.—Roanoke, Va.

Time of Annual Session 1889.—About September 3—the exact day to be definitely fixed and announced by the Executive Committee some months hence.

The next order of business being the nomination to the Governor of

MEMBERS OF THE MEDICAL EXAMINING BOARD OF VIRGINIA

to serve for the regular term of four years, beginning January 1, 1889, Honorary Fellow DR. J. EDGAR CHANCELLOR, of University of Virginia, introduced the following resolution:

Resolved, That the Medical Society of Virginia, desirous of showing their appreciation of the work performed by the Medical Examining Board of Virginia for the term of four years to terminate December 31, 1888, nominate each of the thirty-two regular physicians now representing this Society on that Board, and recommend to the Governor of Virginia to issue commissions in due form to each of those so nominated to serve for the reg-

ular term of four years, beginning January 1, 1889, as members of that Board.

This resolution was unanimously adopted.

The following are the thirty-two members of the regular profession, who are to compose the

BOARD OF MEDICAL EXAMINERS OF VIRGINIA

for the term of four years, beginning January 1, 1889, with their post-office addresses.

State at large.—Drs. T. J. Moore, Richmond, Va.; I. S. Stone, Lincoln, Va.

1st Cong. District.—Drs. S. W. Carmichael, Fredericksburg, Va.; O. B. Finney, Onancock, Va.; W. W. Douglas, Warsaw, Va.

2nd Cong. District.—Drs. Jesse H. Peek, Hampton, Va.; Herbert M. Nash, Norfolk, Va.; James Parrish, Portsmouth, Va.

3rd Cong. District.—Drs. R. A. Lewis, Richmond, Va.; C. R. Cullen, Richmond, Va.; Hugh M. Taylor, Richmond, Va.

4th Cong. District.—Drs. J. Herbert Claiborne, Petersburg, Va.; W. J. Harris, Blackstone, Va.; Hugh Stockdell, Petersburg, Va.

5th Cong. District.—Drs. Rawley W. Martin, Chatham, Va.; W. L. Robinson, Danville, Va.; T. B. Greer, Rocky Mount, Va.

6th Cong. District.—Drs. H. Grey Latham, Lynchburg, Va.; A. Trent Clark, South Boston, Va.; Oscar Wiley, Salem, Va.

7th Cong. District.—Drs. Wm. P. McGuire, Winchester, Va.; J. H. Neff, Harrisonburg, Va.; Hugh T. Nelson, Charlottesville, Va.

8th Cong. District.—Drs. C. C. Conway, Rapidan, Va.; Alexander Harris, Jeffersonton, Va.; Bedford Brown, Alexandria, Va.

9th Cong. District.—Drs. Robert J. Preston, Marion, Va.; R. W. Huffard, Chatham Hill, Va.; S. W. Dickinson, Marion, Va.

10th Cong. District.—Drs. Z. J. Walker, Brownsburg, Va.; H. M. Patterson, Staunton, Va.; G. D. Meriwether, Green Forest, Va.

OCTOBER 25—THIRD DAY.

The Corresponding Secretary, DR. J. F. WINN, of Richmond, presented a circular letter from the Publication Committee having charge of the

REVISION OF THE UNITED STATES PHARMACOPEIA,

requesting this Society, in common with every other regular State Medical Organization, to appoint a Committee of three to act with the Publication Committee of the American Pharmaceutical Association, in perfecting the revision of the volume to be issued in 1890.

DR. R. M. SLAUGHTER, of Theological Seminary, moved that the Committee of three be appointed as requested—carried: The President appointed Drs. R. M. Slaughter, Wm. B. Towles,

of the University of Virginia, and John N. Upshur, of Richmond.

The Treasurer, DR. RICHARD T. STYLL, of Hollins, Va., presented his report for the year just ended, showing a balance on hand of \$229.18.

Instead of a formal "Report on Advances in Surgery," to which task he had been assigned, DR. WM. EDWARD MCGUIRE, of Richmond, read a paper on

PATHOGENIC GERMS OR MICROBES, AND SOME CONDITIONS RELATING TO INFECTION.

He said that the "pathogenic micrococci" of chief interest to the surgeon are those of open wounds, such, for instance, as the micrococcus of syphilis, gonorrhoea, acute infectious osteomyelitis, progressive necrosis, etc. The "pathogenic bacilli" are those of syphilis, tubercle, tetanus, anthrax, ulcerative stomatitis, etc. The baneful influences exerted by these organisms on living bodies have been explained in four ways: Acting as an invading army, they destroy the raw food of the weaker inhabitants (the tissue-cells), which require more complex bodies for their assimilation; or (2) they interfere with the due performance of the depurating organ, and produce disease by preventing the elimination of urea and other final products of repressive metamorphosis; or (3) as microbes, along with all living beings, produce excretion, and this excretion is discharged into the body of the animal in which the microbes live, it would produce deleterious effects as certainly as if the animal's excretions had been retained; or (4), as is most generally accepted, the injurious effects produced by microbes is not due to what they take or excrete, but to what they leave; and this is associated with the demand they make for the oxygen of the tissues. Living and multiplying without direct exposure to air, they obtain their required oxygen from the tissues by which they are surrounded; and when oxygen is withdrawn from such complex chemical compounds as our tissues are composed of, the elements enter into new and abnormal combinations (ptomaines) which are believed to be the really poisonous agents. Depression of vitality of the part attacked is an important factor in the process of infection. An essential condition in the production of local depression is inflammation. Practically, the microorganisms enter the body in the first stage of inflammation. Much depends on the part of the body exposed to infection—some microorganisms infecting only one part of the body, and others another part. Pettenkoffer believes that everything that increases the amount of water in the blood predisposes the individual to infectious diseases.

Under call for "Reports in Chemistry, Pharmacy, Materia Medica and Therapeutics," the Chairman, DR. R. A. LEWIS, of Richmond,

presented the report, prepared by Dr. Joseph M. Whitfield, lately of Richmond, but now resigned and removed to New York, on

ADVANCES IN CHEMISTRY.

Organic chemistry is the branch attracting special study at present.

Incompatibilities should be better known by physicians. Thus, iodol is incompatible with yellow oxide of mercury, and yet with those unfamiliar with chemistry, such a prescription is often written for an ointment. But in a week's time the neat-looking yellow homogenous ointment changes to a dirty grayish mixture. The trouble is the excess of iodide in the iodol is given off and decomposes the yellow mercuric oxide.

Saccharin, or saccharinic acid, the sweetest of all known substances, belongs to the group of coal-tar products, and is antiseptic. It is claimed also that it acts directly on the fourth ventricle, and thereby diminishes the amount of sugar produced in the system. It is a boon to diabetics having the proverbial "sweet tooth." It is dispensed in half to one grain tablets. One grain will make a cup of coffee too sweet for most persons. It combines readily with most alkaloids, such as quinia, morphia, cocaine, etc. As it prevents fermentation, it is used in gastric and intestinal disorders.

Cocaine saccharinate is about four-fifths the strength of cocaine muriate, but has no bitter taste.

Antipyrin and antifebrin are noted as derived from amilide. Antipyrin is a proprietary drug, and cases of poisoning by it have been reported; but no case of poisoning by *antifebrin* has yet come to light, nor does it interfere with the digestive tract as does antipyrin. Besides, its effects in smaller doses lasts longer; it stimulates rather than depresses the vaso-motor and muscular systems; it has no after effects, and it is very much cheaper than antipyrin. Antipyrin is strongly recommended as a prompt hæmostatic, leaving the wound clean.

Phthalates are salts formed by the action of the organic acid—phthalic acid—on vegetable alkaloids. The special advantages claimed for these salts is their great solubility and stability.

Sulfonal, an oxidation product of ethyl-mercaptan with acetone, is tasteless and colorless and crystallizes in large tablets, easily soluble in alcohol and in two parts of water. It is hypnotic in doses of from gr. xx-xxx.

Amylene hydrate, or di methyl-ethyl carbynol, is a tertiary amyllic alcohol—a clear liquid having an ethereal odor and a camphor-like taste. It ranks between chloral and paraldehyde as a hypnotic. It is safer than chloral, as it does not depress the heart or respiratory centres, and has not the nauseous taste nor cause the disagreeable eructations of paraldehyde.

Urethran, or ethyl-urethran, produces sleep like normal sleep, leaves no headache nor gastric disturbances, and only slightly slows the pulse. It is soluble in water and its taste is not unpleasant. Dose for infants from 12 to 18 months old, about 4 grains.

Menthol, or peppermint camphor, is a soluble crystalline salt, looking like Epsom salts, deposited when Chinese oil of peppermint is exposed to cold, forming stearoptine of peppermint oil. It equals thymol as an antiseptic, and hence its use in diphtheria, typhoid and scarlet fevers, etc.

After some notes about cocaine, jambul seed is mentioned as a new treatment for diabetes mellitus. Dose of the fluid extract of the seed, from 5 to 10 minims.

Succinimide of mercury for hypodermic purposes seems to be a valuable preparation. It is a white, silky powder, prepared by heating together ammonia and succinic anhydride, and then adding mercuric oxide. It is very soluble in water and the solution is a permanent one. It is cheap.

DR. H. ROLFE DUPUY, of Norfolk, Va., read the report on

ADVANCES IN MATERIA MEDICA AND THERAPEUTICS.

In reviewing the literature on this subject during the past year, he called special attention to the two great antipyretics, antipyrin and antifebrin, showing their uses and abuses, and the particular indications for each, claiming for the latter the greatest and most varied use. Strophanthus was urged as the great heart tonic, particularly when used in connection with ether, and also with nuxvomica. Attention was called to the great value of ichthyol in skin diseases and rheumatic pains. The literature about salicylate of ammonia was reviewed *in extenso* in connection with the treatment of typhoid and remittent fevers. Salol, sulfonal, sparteine, pichi, jambul and other new remedies or preparations came in for their appropriate share of attention. In conclusion, he condemned the use by physicians of proprietary preparations which did not have attached to the description a working formula for the guidance of the pharmacist.

Dr R. C. POWELL, of Alexandria, read a paper on the

ETIOLOGY OF PYREXIA FROM THE STAND-POINT OF MODERN PHYSICS.

He remarked that no theory based wholly on demonstrated science has yet been offered to explain the high temperature in pyrexial diseases, any attempt to explain the phenomenon by a theory not in harmony with the laws of conservation of energy or correlation of forces is not worth consideration. After a full discussion of numerous theories, he presents the following as his conclusion:

1. The matter of the human body is identical with that of the world around us; and the forces of the human body are the same as those of inorganic nature. This body as a piece of mechanism are more perfect than any other apparatus for the transformation and distribution of energy, with which it is supplied, but possesses no creative power.

2. The relation between combustion and heat is coincidental, and not causal. If heat is the result of collision between carbon atoms and oxygen atoms, this collision must precede that intimate union of such atoms which is termed combustion; and as the effect can never precede the cause, heat cannot possibly be the effect of combustion.

3. The oxidation of tissues *cannot* be exaggerated by the presence of micro-organisms whose very existence is maintained by the *absorption* of oxygen from these tissues.

4. In all *essential fevers*, the pyrexia is probably due to increased molecular motion.

5. The rapid waste of fatty tissue in fever is not so intimately connected with the production of heat as with the production of energy—some of which is manifested in the accelerated action of respiration and circulation.

6. In sympathetic pyrexia, heat is a form of energy which, by reason of traumatic lesions of the nervous system, is prohibited from expending itself in functional activity or motion, and is therefore transmuted into heat, which is the form most frequently assumed by transmutable energy.

7. The only rational way to treat essential fever is to destroy the cause of it; but for agents to cause this destruction, no enthusiastic search will be made until we repudiate the idea that the great object in the treatment of fever is to place the system in the most favorable condition for recuperation after the disease shall have run its course.

Dr. LEWIS G. PEDIGO, of Roanoke City, read a paper entitled

ANTAGONISM BETWEEN AMYL NITRITE AND PRUSSIC ACID.

After certain preliminaries, he gave an account of three representative experiments out of a series that he had performed on lower animals, illustrating the use of amyl nitrite by inhalation as a treatment for prussic acid poisoning. The experiments consisted in administering the poison in large doses—hypodermatically—and beginning the use of the antidote at once by inhalation. Collateral experiments were reviewed in which the poison was given in equal or smaller doses and the antidote withheld. The effects were observed and compared, always showing a remarkably heavy balance in favor of the remedy. In one of these experiments a dog's life was saved by the use of the nitrite of amyl from the action of the same dose which had just killed a similar dog in five minutes and fifteen seconds, without treat-

ment. In commenting on the experiments, a theory was evolved to explain the action and antagonism of the two drugs. The convulsion and arterial spasm of prussic acid poisoning were attributed to paralysis of the inhibitory nerve centers. The relief of these symptoms by nitrite of amyl was accounted for on the supposition that this drug stimulates those centers. The two drugs were shown to antagonize each other in six distinct physiological items, thus proving the amyl to be a more nearly perfect physiological antidote to prussic acid, than is known for any other poison. He suggests the use of the same remedy in cases of poisoning by other cardiac depressants, and enumerated aconite, veratrum viride and gelseminum.

(To be concluded.)

Obstetrical Society of Philadelphia.

Stated Meeting, October 4, 1888.

THE PRESIDENT, T. M. DRYSDALE, M.D.,
IN THE CHAIR.

(Continued from page 679.)

DR. B. F. BAER read the following report of

TWO CASES OF MULTILOCLAR OVARIAN CYSTOMA of unusual size and very rapid growth. Mrs. T. was sent me by Dr. J. A. Clark, of Bedford, Pa., and on July 31st entered my private hospital. She is æt. 28 years; married; has had two children after normal labors, the youngest being six years of age. About nine month previous to this date, she was attacked with severe pain in the right ovarian region and was confined to bed for several weeks. Her menses had always been regular, but at this time the flow was profuse and continued two weeks. Soon after this attack of pain and metrorrhagia she noticed a swelling in the painful region, on the right side. She rapidly increased in size and began to lose flesh, and occasionally to have attacks of pain and metrorrhagia similar to the one noted above, the flow for several occasions lasting for a month. Her abdomen was enormously distended, especially in the upper portion. It was rather symmetrical, dull on percussion all over the anterior and lateral portion except in the lumbar regions, where slight resonance was observed. There was fluctuation in the lower part, but in the upper portion it was very obscure. The skin on the lower surface of the abdomen was in a condition of elephantiasis.

Vaginal examination revealed the uterus slightly retroverted, rather mobile, and gave a sound measurement of three inches. The lower surface of the tumor could just be felt by the vaginal examination. The patient had a very weak pulse, indeed it could not be felt at all at

the left wrist and she had great dyspnoea on the slightest exertion.

Operation was performed on August 2nd. I was assisted by Drs. J. C. Bowen, G. H. Franklin, J. A. Clark and H. C. Bloom. An incision three inches in length was made in the usual position. The skin at the point of the incision was fully half an inch thick and very vascular and considerable subcutaneous adipose tissue was present. As soon as the tumor was reached it presented the appearance common to ovarian growths, but it was found to be closely adherent to the abdominal wall. After separating as far as the finger would reach, the tumor was punctured with Tait's large trocar, and about four gallons of greenish fluid drained away; but only the lower portion of the tumor collapsed, the greater and upper portion remained as before. This was punctured in a number of places without removing the instrument from the cavity which had been drained, but nothing followed. The opening in the tumor was now enlarged and the hand introduced and the multilocular condition broken down, large pieces of semi-solid substance being torn loose from the cavity of the tumor and brought away, together with a great deal of semi-fluid debris. As soon as room was gained the hand was carried outside the tumor, when it was found to be adherent to the liver, stomach, and everything with which it came in contact. These adhesions were carefully separated and after considerable effort the remainder of the tumor was finally brought out through the incision, which had been previously increased to three and a half inches. The pedicle, which was found to be thick and quite vascular, was transfixed and ligated and the tumor cut away. The cavity was irrigated with filtered boiled water, as much as two gallons being used. The irrigating tube was carried in every direction until the water returned clear. The right ovary was not removed, it being in apparent health. The wound was closed around a drainage tube. There was considerable shock. The pulse could not be felt at either wrist and it was two days before it returned, although the patient seemed to be doing well. The usual after treatment was carried out and the patient has made an excellent recovery. She went home (250 miles) on the twenty-seventh day and still remains in good health. The temperature never rose above 100° and the drainage tube was removed on the second day. The tumor was a multilocular cyst and weighed about ninety pounds.

On September 5th I was asked by my friend Dr. R. Armstrong, of Lock Haven, to meet him in consultation in a case of abdominal tumor, which he stated was in such extreme condition that he feared she might not live until my arrival.

I saw the patient on September 6th. She is 21

years old and single; puberty had occurred at twelve and menstruation had always been profuse, coming on every three weeks and always attended with some pain; she did not consider this abnormal, and so far as she knew was perfectly well up to four months previous to the above date. In the latter part of April of this year after unusual exertion about the house, she was suddenly attacked with severe cramp-like pain in the right iliac region, so severe indeed as to alarm the neighbors by her outcries. This attack occurred about the time of her expected menstruation and continued until the flow followed, when she gained considerable relief. But she remained ill from that time, being able to go about, however, in the intervals between the series of attacks of pain of similar character which now followed. Within two weeks after the first attack she noticed that her abdomen was increasing in size in the painful region and from that time to the present, just four months, her abdomen has grown to an enormous size. I found her occupying a semi-recumbent posture and breathing with difficulty. She was emaciated to such a degree, and the tumor was of such size, that she was almost hidden from view beneath it. The surface of the abdomen was purple from interference with the capillary circulation and the veins were greatly distended. The abdomen was symmetrical and smooth. Fluctuation was rather obscure. There was dulness on percussion all over the anterior and lateral surfaces of the tumor, except at a point far back in the left lumbar region, where slight resonance was found. On the upper right border of the tumor, in the region of the liver, there was an apparently solid mass, shaped somewhat like the liver, suggesting the possibility that the cyst had grown from that organ. This was given more prominence on account of the rapidity of the growth. The patient was unable to retain anything on her stomach; she had not slept except at short intervals, for weeks. Her bowels were constipated and the urine was passed frequently and in small quantities. Her pulse was 140 and very feeble. Her expression was an appealing one and she begged to be relieved.

A tablespoonful of whisky was given and repeated in two hours, just before the administration of the anæsthetic. I was ably assisted in the operation by Drs. Armstrong, Ball, and Watson, of Lock Haven. An incision two inches in length was made. The surface of the cyst was adherent to the peritoneum. After separating the adhesions as far as I could I plunged a large trocar into the tumor. But the contents were semi-solid. I therefore cut through the cyst-wall and proceeded to break up and remove the contents. The cyst was adherent to everything it touched, liver, stomach and other viscera, but the adhesions were weak, and in ten minutes' time the tumor was removed and the pedicle, which was thick and vas-

cular, was ligated. The omentum was so firmly adherent to the cyst that it was ligated and amputated. The friable cyst-wall was ruptured in many places and a great deal of the viscid semi-fluid material escaped into the abdominal cavity, but I did not lose time in trying to prevent this. When the tumor was removed what was left of the patient was an exceedingly small portion. The emaciated abdominal walls lay close to the spinal column and sunk into the pelvis. She looked more literally "nothing but skin and bones," than anything I had ever seen before. The abdominal cavity was thoroughly washed out by irrigation through a fountain syringe, and I was careful to pass the nozzle high up among the intestines and under the surface of the liver and diaphragm. The water returned clear and the incision was closed around a drainage tube and the patient returned to the bed with a better condition of pulse and appearance than she had before the operation. She did not show any evidence of shock and was conscious almost as soon as she was placed in bed. Her body was so emaciated that it was necessary to pack with cotton about the pelvis and along the spinal column, as the bones almost projected through the skin, and at several places bed-sores were apparent. The R. ovary seemed smaller even than its natural size and appeared thinner; it was therefore not removed. The after history of the case has been without event. Her temperature never rose above 100° and was normal on the third day after the operation. The pulse gradually diminished from 140 and was normal on the fifth day. The drainage tube was removed within thirty-six hours after operation. The sutures were removed on the eighth day, when union was found complete, except at the lower portion where the drainage tube had been, and this has since healed. She began taking solid food on the third day and on the fourth day her bowels were moved. The tumor weighed about 75 lbs.

The points of considerable interest in these cases are the location, character, and severity of the early symptoms, as well as the location of the tumor when first noticed (in the right side), while the tumors were of the left ovary, the right being perfectly healthy; the large size and very rapid growth of the tumor; the rapid recovery of the patients although in extreme condition, especially of the case last mentioned; the fact that the two cases are alike in nearly all particulars, the only difference being that in the second case the rapidity of the development was much greater, and the severity of the symptoms likewise greater; and lastly, the method of removal of the tumor, that is, the breaking up of the semi-solid contents with the hand, thereby permitting their removal through a very short incision. I wish here to call attention to a fatal case which occurred in my practice several months ago and which forcibly

illustrates that there may be danger in introducing the hand for the purpose of breaking down contents of the tumor, not knowing exactly the location of the intestines. In the case referred to the friable wall of the main cyst had ruptured and some coils of intestines were found to be in the cavity and closely adherent to the more solid portion of the contents. Very careful manipulation was necessary to separate the bowel, which was finally done after considerable time had been spent in the effort. Ordinarily, however, where the cyst has not previously ruptured the procedure is a safe one when due care is observed.

DR. M. PRICE reported a case of

PYOSALYNX WITH RUPTURE.

On the 6th of September I was called to Mrs. —, with symptoms of miscarriage, with pains, hæmorrhage and slight odor to the discharge. She refused to have an examination, saying she knew she was not pregnant. I left her with the understanding that when she was ready for me to examine her to send for me. On September 10, I was again called, and found her in great pain; the discharge of blood and broken down placenta were of the most offensive character. She stated that she had been perfectly regular up to her last period, which was delayed about one week. She had considerable fever, a temperature of 102° , and had had that morning a severe chill. On examination the uterus was found about four inches in depth, with part of a rotten placenta adherent to its right posterior wall. The uterus was in good position and perfectly movable, with both tubes enlarged and thickened, and at this time could not have been adherent to any surrounding structure. I removed the placenta with considerable difficulty, used hot water irrigation with boric acid in the uterine cavity, which, for a time, gave her great relief. These irrigations were continued, and the uterus washed out twice a day for three days, all this time the tubes continuing to enlarge, until they must have contained several ounces of matter, and could have, at this time, been easily removed. The irrigation into the uterus were discontinued, and those of the vagina were kept up. I became very much alarmed at her condition, and stated to the husband that an operation was needed to save his wife's life. This he refused, and begged that I should do all I could without the operation. I yielded to his request much to my regret, for I felt that nothing but an immediate operation and removal of the tubes, which then would have been possible, as there had been little if any leakage up to that time into the peritoneal cavity, would save her life. I believe that any man treating a case of this kind with the symptoms as positive and the indications as plain as they were in this case for operation, should have retired from the case, for by so doing, he clearly indicates that his mind is

made up as to the treatment and the only chance to save, and by so doing, shows to the medical attendant who may be called to the case, the proper line of treatment, and if he does not take the warning, the post-mortem will follow and show who was right. There were several well-marked changes in her condition, indicating rupture or leakage from the tubal abscess, and her condition steadily grew worse until the 20th, when in consultation with my brother, we persuaded the family and the patient to let me operate and give her that chance for life, as she was in a very bad septic condition. As the consultation was at a very late hour at night, she was opened early the next morning (21st). I found the internal organs matted together, uterus much enlarged, both tubes enlarged and ruptured, adherent to everything they touched, pelvis full of pus cavities, pus cavities almost up to the kidneys on both sides; everything in a semi-gangrenous condition; but little bleeding from ruptured adhesions or from wound in opening abdomen, which is never a good indication. A great quantity of pus was evacuated, at least two pints, of the most offensive character. Irrigation and drainage were used. The patient was a very large woman, consequently the longest drainage tube we could find was used. She rallied from the ether, and for the first six hours there was discharge from the drainage tube, two pints of very offensive serum. It gradually lessened in quantity, but increased in offensive character. A cleaning of the tube was made every half hour; before cleaning warm boracic water was injected through the tube. It improved matters only for the moment. Patient died twelve hours after the operation. Present at the operation: Drs. Joseph Price, E. W. Cushing, of Boston, Atherton, Toronto, Roseburg, Hamilton, Ontario.

DR. W. H. PARISH said that his remarks on this subject of pelvic abscess read at the recent meeting of the American Gynecological Society had been misquoted. He had stated there, and wished to repeat here, that these abscesses should be opened very early. If operation was not resorted to the patient would most probably either die or become a confirmed invalid. He was not one of those who believe that pus always originates in one particular point in the pelvis. He did, however, believe that the large majority of cases occur because of pus primarily in the tube. He believed, also, that an uncertain number of cases occur from pus originally formed in the areolar tissue, beginning probably because of lymphangitis of that particular locality. The question arises as to how best to operate in these cases. He said that there could be no absolute rule of procedure. He believed that, in the majority of cases, it was wiser to make an opening in the median line and explore the peritoneal cavity, unless we are very certain that the abscess is not

in the tube or ovary. If we are sure that there is no involvement of the appendages and that the pus is not intraperitoneal, the abscess may be opened without going into the cavity. He called attention to a procedure which he had adopted in a few instances, where small abscesses were located in pelvic areolar tissue. In one instance Dr. Longaker made an incision in the median line. The tubes and ovaries were found free from pus, but of course congested. With the fingers within the abdomen he felt in the anterior pelvic wall an abscess. An incision was made over Poupart's ligament as for ligature of the external iliac. Then passing deep into the pelvis, pus was reached some distance below the brim of the pelvis. In another case there was an indurated mass apparent above the left half of the pelvis, not very recognizable through the vagina, except on very deep pressure. An incision was made above Poupart's ligament. After cutting through very dense tissue, he came to a minute cavity which contained no pus, but a somewhat serous fluid containing flakes of lymph. These are only two of a considerable number of pelvic abscesses in which he had operated, and he had never regretted operating early.

DR. J. M. BALDY wished to take this opportunity of emphasizing views which he had expressed before the recent meeting of the American Gynecological Society. He did not agree with Dr. Parish as to the pathology of this affection. He granted that there was the possibility of an abscess occurring in the pelvis, such as occur in other parts of the body from the scalp to the foot, but that these must be most rare. The gentlemen connected with what Dr. Parvin had been pleased to call "the Philadelphia Dispensary School of Surgery" had now done over one hundred of these operations, and had not yet in a single case come across one which had not begun primarily in the tubes or ovaries. In every case the diseased mass removed has been tube, ovary and other tissues involved. (Dr. Parish, at this point, asked wherein his views differed from those of Dr. Baldy?) He had to leave that to be inferred from what Dr. Parish had said. In regard to treatment he must again dissent from the views expressed. He thought that an absolute rule *could* be laid down. Where pus was found in the pelvis, early or late, the proper procedure was to open the abdominal cavity, and where it was not possible to remove the seat of the disease, proper drainage should be established. However, it would be found comparatively seldom that the abscess could not be taken out by a bold operator.

DR. JOSEPH PRICE thought that he understood Dr. Parish. He himself had said repeatedly that we might have an abscess in any part of the body from the scalp to the matrix of the nails, we may have it in the cellular tissue of the pelvis as well as in the axilla or neck, but he must hold to

what he had said, that in all the pelvic abscesses that he had seen he had not found one not due primarily to tubal disease. Among the recent papers on the subject, one calls attention to the treatment by drainage through the vagina. He did not see how this will avail much in bilateral accumulations. You may evacuate half of the tube, but you have left a condition of affairs such as is found in an old bubo. In pelvic abscess we have just the condition of affairs which the surgeon is asked to treat in the groin, axilla or popliteal space. In such a case he would remove the disease by a clean enucleation and perfect a cure. He had not seen a case of pelvic abscess which could not be removed in this way and he should say that such cases did not exist. One gentleman at Washington went so far as to say, that after drainage by vagina in a case of double pyosalpinx, recovery had followed—the woman had borne children. He might as well have said she had conceived, notwithstanding her husband had previously been castrated.

DR. M. PRICE remarked that it was a question whether you could say that the tube was diseased or not, by simply looking at it. He remembered a case a few weeks ago, where the tube was congested and inflamed. It seemed to be simply swollen, but on pressure there was forced from the fimbriated end a drop or two of as perfect gonorrhœal pus as could be found anywhere. If he had not seen the discharge, he should have thought that there was no disease save congestion.

(*To be concluded.*)

FOREIGN CORRESPONDENCE.

Pettenkofer's Views on Zymotic Diseases and Quarantine.

[The following is translated from manuscript given by Professor von Pettenkofer to Dr. Horatio R. Bigelow, for THE JOURNAL.]

For thirty years I have held the opinion that all the so-called zymotic infectious diseases (typhoid fever, cholera, yellow fever, etc.) are caused by lower organisms, and that the specific germs are spread by human intercourse. I differ from the contagionists, however, in the important particular that I place the causes of the epidemic diseases, so far as they show a striking dependence upon locality and season, not in people, but in their surroundings.

I classify infectious diseases as entogenous and ectogenous: entogenous when the virulent infectious material is simply transferred from the infected to the healthy person, and infects him (such as small-pox, syphilis, etc.); ectogenous when the germ spread by human intercourse must first go through a certain stage outside the human organism in order to increase and become virulent,

and become capable of infecting, as for example malaria.

It is not the cholera patient nor the yellow fever patient that infects, but the cholera locality and the yellow fever locality. Physicians and nurses, therefore, are no more affected than persons who do not come at all in contact with the patients. In a hospital containing cholera or yellow fever patients, but which is not a cholera or yellow fever locality, the nurses and attendants remain healthy, and other patients are not infected. Of course a hospital, just as well as other houses, may become an infected locality, and in that case attendants and other patients may become infected; a so-called house epidemic breaks out, but in this case the infection is due to the locality, not to the patients. So it is in barracks in which epidemics break out without a sick person having been previously brought there.

House epidemics in hospitals in which cholera patients are assembled are not more frequent nor more severe than house epidemics in barracks in which every suspicious case of diarrhœa among the soldiers is immediately removed—isolated.

For infection there must be not merely the presence of infectious material, but there must be also a certain quantity of it. It is true, so much locally produced infectious material may be carried from cholera and yellow fever localities, in individual cases, by human and other means, into other places, that infection is produced; but this seldom occurs, and does not cause epidemics, but sporadic cases only, when the germs do not fall on fruitful soil, and the place is not disposed to the ectogenous spread of infecting material.

There are places that always have immunity from imported infectious material (such as Versailles, Lyons, etc.), but the affected places have immunity from ectogenous development of the imported germ, which alone is capable of causing infection, only temporarily and now and then.

As in places in which cholera or yellow fever is endemic there is often a considerable length of time in which there are no patients, or they are very few, without the specific poison having disappeared from the place, and then again there are numerous cases after a little time, without the infectious material causing them having been newly imported, so may the specific material from cholera or yellow fever localities, carried to other places by human intercourse, cause an epidemic after it has had time for development (which time, according to Pettenkofer's observations, may be many months).

For this reason we seldom find the trace of personal or local connection between the first cases in a country or in an active commercial city, as well between one another as with immediately preceding foreign cases, or cases brought from without.

For this reason also all quarantine regulations of land and water, all disinfection and isolation,

which are limited to the known cholera or yellow fever patients, are always ineffective.

Pettenkofer cites many facts going to show that cholera epidemics do not become more violent and do not last longer when intercourse with cholera patients is not limited to the least extent, and when neither isolation nor disinfection are practiced. Where these measures seem to have been used, the local and temporary disposition of the locality was wanting. So soon as there is this disposition in a place, and the specific material is present, the disease breaks out, and all measures based on the grounds of the contagionists are futile.

In order for the disease to occur there is necessary not only a sufficient quantity of the specific infectious material, but also an individual disposition. When a number of people are exposed to the same influences of intercourse and infected locality, all of them are never attacked, but only a small number, corresponding to the more or less developed individual disposition. The duration (?) of the disease—even in a slight degree—protects for a considerable time against repeated infection.

Some are inclined to explain the temporary outbreak and the gradual subsidence of a cholera epidemic in a place by the existence of individual disposition and its subsequent exhaustion. This is a mistake, however, for were it true there would be no places having immunity, whose inhabitants could pass through the disease, and after the introduction of the poison severe epidemics would certainly break out. Nor can the extinction of the local epidemics be explained on the theory that that there are no more disposed persons in the place. The explanation must be that the place ceases to produce virulent infectious material. When this happens disposed persons come in greater number from without, and the epidemic is extinct (Leipzig, 1866, and Messina, 1887).

The occurrence and conduct of cholera on board ships, in the light of later examination, are very much against the contagionist and more in favor of the locality views.

The drinking-water theory is applicable neither to cholera, nor to yellow fever, nor to typhoid. In non-sterilized water cholera bacilli and typhoid bacteria perish quickly, partly for want of suitable nutritive material, and partly also from coming in contact with the non-pathogenic water bacteria; and even when they are viable in a cholera or typhoid stool in wells or water-pipes, the infectious material is so extraordinarily diluted, that infection from the use of such water cannot occur. Hitherto there has been no experiment on animals that has succeeded in infecting one of them with pathogenic micro-organisms (of anthrax, chicken cholera, etc.) through drinking-water; and this is in complete accord with epidemiological facts. Nevertheless, Pettenkofer is enthusiastic on the subject of good drinking-water,

because clean and pure water is generally a deeply felt want, and is a necessity not merely in typhoid and cholera places, but in all other places.

As regards the prophylactic measures, these should be directed: 1. Against the spread of the germs of specific disease by human and commercial intercourse. 2. Against the individual disposition. 3. Against local disposition.

The spread of the specific germ can be hindered only by the discontinuance of all personal and commercial intercourse with infected places, but never by a mere watching and regulation of such intercourse, since this is never, in the bacteriological sense, fungus-proof. As a rule the germs are already spread before a patient is discovered in a place. All the rules in this direction have, therefore, been without good result, whether applied to land or water. The cessation of all intercourse for a long time, for a series of years, even were such a thing possible, would be a greater misfortune than cholera and yellow fever.

It would certainly be better if people could be freed from the individual disposition, or even if this could be lessened, as in the case of small-pox by vaccination. It is possible that an inoculation material may be found for cholera, but thus far none has been found to serve the purpose.

We have well-tried measures against local disposition. The most important part of the local disposition is uncleanness of the soil due to human excreta. Cleansing and keeping clean the soil upon which our dwellings stand is the best prophylactic measure against cholera and typhoid epidemics, and probably also against yellow fever. Wherever there is proper house-drainage and removal of every kind of excrement and garbage by canalization, removal of all privy vaults, and of all material that will not float, the disposition to these diseases is either entirely destroyed or very much diminished. England, for example, in spite of its unbroken and very free communication with cholera-infected places, and in spite of several important cases of cholera, since 1866, in consequence of its sanitary improvements, it has had no epidemic of cholera. The City of Munich, formerly known to the whole world by reason of its numerous cases of typhoid fever, has now only 14 cases per 100,000 yearly, instead of 300 per 100,000 as in former years. There are places so fortunate as to have a natural immunity against cholera. But even those places that have not natural immunity, can be rendered free of disposition by hygienic art (such as Fort William at Calcutta).

But the measures for giving immunity to a place should not be delayed until an epidemic breaks out, but should be carried out beforehand, so as to be truly prophylactic. An unclean soil cannot be made clean suddenly, even when man ceases to pollute it further, but it requires time for self-cleansing; just as a field does not become

suddenly unfruitful when we cease to fertilize it. It requires time, and more or less according to the quality of the soil.

These and many other important epidemiological facts are laid down in Pettenkofer's writings. The most important are to be found in his two recent works: "Zum gegenwertigen Stand der Cholerafrage," Munich, 1887, and "Der epidemiologisches Theil der Berichtes über die Thätigkeit der zur Erforschung der Cholera im Jahre 1883 nach Aegypten und Indian entstanden deutschen Commission," Munich, 1888.

Local factors are more prominent in yellow fever than in other infectious diseases. In yellow fever the local limitation is much narrower. The epidemics usually occur on the seashore and on the banks of large rivers, and do not extend far inland. Temperature, brakish water, or soil water containing a good deal of salt, in the soil has a local influence.

The researches of Professor Billings, of the University of Nebraska, in regard to cattle plague or Texas fever and yellow fever show many analogies to the views of Pettenkofer.

NECROLOGY.

Henry B. Sands, M.D.

HENRY BERTON SANDS, probably the best known of the surgeons on the Atlantic seaboard, died of apoplexy, in his carriage, November 18, with an appalling suddenness. He was born Sept. 27, 1830, in New York City, and was throughout life identified with it as a resident. His father, also a native of the city, was long and favorably known as one of its most trustworthy apothecaries. He was from the very beginning of his career an earnest and enthusiastic student, with somewhat of an outside bias for instrumental music, having in early life even filled the position of organist in one of the leading churches.

Dr. Sand's name was long associated with the New York College of Physicians and Surgeons as Demonstrator of Anatomy, Professor of Anatomy, and Professor of Surgery. Besides these positions, he was connected with nearly all the hospitals of that city, either as Visiting or Consulting Surgeon. His society membership was also extensive.

As an operator, Dr. Sands probably had no superior as a rapid, graceful and skilful manipulator—these qualities added to an almost unerring judgment and a certain diagnostic instinct, gave him a fame, which out-leaped the barriers of his home. His success as a laparotomist was almost unique, and there were but few cases of appendix vermiformis disease in his native city or environs which were not in some way brought to his notice.

Of a marvellous industry, and unimpeachable punctuality conjoined with a devoted loyalty to his profession, and an ever-present modesty, he was a favorite consultant with his brethren far and near. His reputation certainly rests upon a very secure basis.

MISCELLANEOUS.

A DIPHTHERIA SCARE prevails at Alden, Iowa, and the town schools have been closed.

DR. D. HAYES AGNEW will, it is reported, soon resign the Chair of Surgery in the University of Pennsylvania.

CONGENITAL DEFECTS.—Dr. R. R. Williams, of Manning, Ia., informs us that in October, 1888, near Manning, a child was born with but *one* hand and wrist.

BAD MEAT IN OMAHA.—The Omaha Meat Inspector's report shows that 3,485 pounds of diseased meat and six gallons of oysters have been condemned during the past month.

NORTH CENTRAL ILLINOIS MEDICAL ASSOCIATION.—The fifteenth annual meeting of this Association will be held in the M. E. Church, LaSalle, Ill., on Tuesday, December 4, 1888, at 10:30 A.M.

THE SOUTHERN ILLINOIS MEDICAL ASSOCIATION met at Duquoin on Nov. 15. On the second day, after an interesting and profitable meeting, the Association adjourned to meet in Metropolis on June 15, 1889.

DEATH OF AN ALLEGED CENTENARIAN.—Mrs. Hannah Sharkey, the oldest woman in Ohio, died at Youngstown, Ohio, a few days ago. She was said to have been 111 years old, having been born in Cork, Ireland, in 1777.

UTICA MEDICAL LIBRARY ASSOCIATION.—The following are the officers for the ensuing year: President, Dr. J. G. Kilbourn; Vice-President, Dr. Chas. J. Wagner; Secretary, Dr. D. C. Dye; Treasurer, Dr. H. Quin.

SOUTH KANSAS MEDICAL ASSOCIATION.—The twenty-sixth semi-annual meeting of the South Kansas Medical Society met in Hutchinson on November 13. There was a large attendance of leading physicians from all over the southern portion of the State.

SCARLET FEVER.—A dispatch from Jamestown, Dak., says that an epidemic of scarlet fever is raging there. Churches, Sunday-schools and public schools have been ordered closed during the prevalence of the disease. A number of deaths have already occurred.

A PROBABLY FATAL ACCIDENT to Dr. Nathan Rogers, of San Francisco, occurred on November 2. His horses ran away, overturning the carriage and throwing Dr. Rogers out. His head struck the curbstone, resulting in a fracture of the skull which is pronounced fatal.

CREMATORIES.—At the congress of the advocates of cremation recently held in Vienna it was stated that there are throughout the world fifty crematories, half of which are in the United States, twenty in Italy, and one each in Germany (Gotha), England, France and Switzerland.

A SCHOOL OF DENTISTRY FOR NEGROES, we learn from a Chicago newspaper, has been established in Nashville, probably as a department of the Meharry Medical School. The Meharry School and Leonard Medical School, of Raleigh, N. Ca., are doing good work—better than the majority of medical schools for white people.

LEPROSY IN DAKOTA.—There is a case of leprosy at Harold, Hughes county, Dak. The subject is the child of Mrs. Bausum, who was a missionary to China when the child was born. The case was examined in New York a year ago and pronounced to be one of leprosy. The members of the afflicted family are allowed no communication with the neighbors.

POWER OF THE IMAGINATION.—DR. DURAND, wishing to test the effects of the imagination on health and disease, experimented on a hundred patients, to whom he gave a dose of sweetened water. Fifteen minutes after he entered, apparently in great excitement, and announced that he had made a mistake, having administered a powerful emetic, and he directed that preparations should be made accordingly. Eighty out of the hundred patients were thoroughly ill, and exhibited the usual results of an emetic.

ARCHIVES OF GYNÆCOLOGY.—Seven hundred and twenty-eight is the record in numbers of the articles printed during 1888 in the *Archives of Gynecology* on the special subjects of its title. It is the aim of the editors to publish all current thought in these departments of medical knowledge. The publishers, Leonard & Co., 141 Broadway, New York, do not send sample copies, but if you are not pleased with the first number it may be returned and the order erased. Subscription \$3.00 per annum. Payment is not asked till end of the year.

THE CAUSE OF ILL-TEMPER has been discovered by a dress-reform lecturer, who does not consider it an evidence of bad disposition. She says that "oftener than not it is owing to bodily discomfort proceeding from improper dressing, and that wives would all be sweet-tempered if they were properly attired and took sufficient exercise." There is probably a good deal of truth in this. Improper and uncomfortable dress and indigestible food are sufficient to cause ill-temper; and if ill-temper be given the rein while food is taken indigestion will result sooner or later.

"ELECTRIC PROSTRATION" is the name given to a disorder which troubles workers under electric lights. Severe cases are reported from Creusot, France, where an electric furnace is used for quickly heating metals. The light exceeds 100,000 candle power, and the men suffer from it, not from the heat. After one or two hours the workers have a painful sensation in the throat, face, and temples, the skin becomes copper red, and an eye irritation begins that lasts forty-eight hours, the discharge of tears being copious. After five days the skin peels off. Dark-colored glasses somewhat mitigate the effects of this tremendous light, but not entirely.

CONSULTATION BY TELEGRAPH.—The Canadian Pacific Railway Company's telegraph was on Nov. 18 brought into service in a way that not only afforded a good illustration of the extent of the system, but furnished a unique example of the possibilities of modern science. Lord Ennismore, heir to the Earldom of Listowell, is lying at the point of death in the hospital at Victoria, B. C., with typhoid fever. Through the aid of Sir Donald A. Smith, who is now in London, a telegraph circuit was formed from London to Victoria by the Mackay-Bennett Cable and Canadian Pacific Railway telegraph, and Sir Andrew Clarke, the distinguished London physician, was placed in direct consultation with Dr. Hamington in Victoria. A conversation lasting three hours, concerning Lord Ennismore's condition, was carried on. An unbroken circuit was worked from Victoria to the cable office in New York, where the telegrams were repeated to London. Replies were received in three and four minutes.

HOMICULTURE.—A writer in the *Nineteenth Century*, taking the cue of the impulse to discuss human culture, makes some suggestions under the heading "Homicul-

ture." He believes a good deal could be done by directing public attention to the laws that underlie the improvement of stock. He also urges that before a marriage permit is allowed parties should be compelled to submit to a medical examination, to show that they are not laboring under hereditary diseases. Beyond this he would have the absolute prohibition of habitual criminals from propagating their kind. These suggestions have been to some degree urged before by Dugdale, but they are timely. No question is of more importance than the improvement of humanity. We have traced our ills to heredity. Our remedies must correspond. Probably all suggestions at present will be crude and premature, but it is nonsense to suppose an evil exists without a possible cure.

DIPHTHERIA CARRIED BY A TURKEY.—A fowl with diphtheria was brought to the house of a veterinary surgeon on April 24, and died on the 29th. The feeding and nursing of the bird devolved on a lad aged 14, who was assisted by his brother, aged 5. On the evening of May 11 the writer was called to see the little boy of 5, who had been poorly for a day or two. He had enlarged cervical glands on the left side, which had come on rapidly. He was a delicate little fellow, with fair hair and anæmic aspect. The fauces were more or less covered with diphtheritic membrane, the left tonsil more especially. Under the administration of biniodide of mercury and iron the throat symptoms cleared up and the child made a good recovery. On the day after this case was first seen the boy who fed the fowl was very feverish and had similar patches over his fauces, but not to the same extent as his brother. A sister, aged 9, had also a similar explosion on the fauces. On the 18th the mother, who nursed them, was attacked and was similarly treated. They were all kept well up with beef-tea and stimulants.—*British Medical Journal*.

Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department U. S. Army, from November 10, 1888, to November 16, 1888.

By direction of the Secretary of War, the retirement from active service this date, by operation of law, of Col. Elisha I. Baily, Surgeon, under the provisions of the Act of Congress approved June 30, 1882, is announced. Col. Baily will repair to his home. Par. 1, S. O. 266, A. G. O., Washington, October 14, 1888.

By direction of the President, Lieut.-Col. Basil Norris and Major Henry R. Tilton, Surgeons U. S. A., are detailed as members of the Army Retiring Board appointed to meet at San Francisco, Cal., by War Department order dated October 27, 1888, published in S. O. 253, October 30, 1888, from Hdqrs. of the Army, vice Col. Elisha I. Baily, Surgeon, and Capt. John J. Cochran, Asst. Surgeon, hereby relieved. Par. 13, S. O. 261, A. G. O., Washington, November 8, 1888.

Major Ely McClellan, Surgeon, is relieved from duty at Jefferson Bks., Mo., and will report for duty at Chicago, Ill., as attending surgeon and as examiner of recruits. Par. 13, S. O. 261, A. G. O., Washington, November 8, 1888.

Major John H. Bartholf, Surgeon, is relieved from further duty in the Dept. of Texas, and will report to the commanding officer at Plattsburgh Bks., N. Y. Par. 15, S. O. 26, A. G. O., Washington, November 8, 1888.

Asst. Surgeon W. H. Arthur, upon being relieved by Acting Asst. Surgeon J. L. Ord, will proceed to comply with par 21, S. O. 250, c. s., Hdqrs. of the Army. Par. 5, S. O. 123, Hdqrs. Dept. of Ariz., Los Angeles, Cal., November 5, 1888.

Official List of Changes in the Medical Corps of the U. S. Navy for the Week Ending November 17, 1888.

P. A. Surgeon Robert Swan, ordered before Retiring Board 19th inst.

ORIGINAL ARTICLES.

TRACHEOTOMY IN PSEUDO-MEMBRANOUS LARYNGITIS.

Read in the Section on Diseases of Children, at the Thirty-ninth Annual Meeting of the American Medical Association, May, 1888.

BY CHARLES G. JENNINGS, M.D.,
OF DETROIT, MICH.

In the city of Detroit during the year ending May 31, 1887, there were recorded in the health department eighty-two deaths resulting from membranous croup, and thirty-eight deaths from diphtheritic croup, a total of 120 deaths from pseudo-membranous laryngitis.

A certain number of cases of pseudo-membranous laryngitis, classed as diphtheria cannot, of course, be included, and for this reason the number given is probably a little below the correct one. During this period, as learned from careful inquiry of the physicians of the city, there were not more than fifteen operations of tracheotomy and intubation performed for the relief of this disease. It will thus be seen that in that city, only one child in eight suffering from laryngeal stenosis, had given to it one of the only two therapeutic measures that would give it a chance for its life.

Although in some communities, operative interference in pseudo-membranous laryngitis may be more popular than in Detroit, it is probable that the figures from that city fairly represent the relative number of operations to cases of pseudo-membranous laryngitis in the large cities, while in the country the relative number is much lower.

Thus, in the year 1884, the mortality from croup alone, in twenty cities of the United States, with a population aggregating 7,051,000 was 2,819. Including the many deaths returned as diphtheria, diphtheritic laryngitis, etc., it will be seen that the annual mortality from pseudo-membranous laryngitis in the United States must be at least 6,000. So far as I learn, the latest published collection of statistics of tracheotomy and intubation performed in this country does not aggregate 2500 cases.

Operative interference, then, in pseudo-membranous laryngitis is not popular.

Considering the frequency of croup, its great mortality when left to medical treatment alone,

and the average percentage of recoveries after operation, there is no single operation in surgery that can save so many lives as tracheotomy, and it is difficult to understand why the profession is so slow to take it up.

Of the various objections to the operation, real and imaginary, which have been raised from time to time, and which evidently still hold sway over the minds of many practitioners, it is unnecessary for me to speak. They are familiar to you, and have been refuted by able writers, and the facts remain that pseudo-membranous laryngitis, when it has reached the stage demanding operative interference, is almost invariably fatal, and that tracheotomy or intubation can save from 20 to 50 per cent. of the cases operated upon. With such statistical evidence in its favor, arguments against operative interference in croup are powerless.

The objections to tracheotomy are no greater than the objections to many other surgical operations, and if applied to them would put an end to operative interference in all grave conditions. In the laryngeal surgery of the adult such objections have no weight, as we find in all diseases attended by laryngeal stenosis, tracheotomy is performed either as a palliative or curative measure. Even in carcinoma of the larynx, when nothing can be gained but a little prolongation of a miserable life, it is always performed.

I believe, then, that if croup were a disease of adult life instead of childhood, tracheotomy would be one of the most common operations in surgery. Children with this disease unable to demand relief, fall victims to the sentimental sympathy of their parents, or the hesitancy of their physicians. Too often it happens that the physician proposes the operation, the patients object, and, by his half-hearted advocacy, the physician encourages the objection. In my short experience I have seen this happen so many times that I have come to look upon it as the chief reason for the infrequent performance of the operation.

I fully realize the difficulties which surround the physician when he is urging operative interference. It is an emergency for which parents are rarely prepared and they instinctively reject it. The physician's duty is not done when he

simply proposes the operation and then takes this instinctive objection as final. To the grief-stricken parents, the average chances of recovery after either intubation or tracheotomy seems very small indeed, and hardly worth the trial, and it is our duty to show, by a frank and hopeful statement of the facts, the great value of the operation, and the earnest surgeon fully believing in this, but rarely will fail to overcome opposition.

Until the introduction of intubation by the remarkable labors of Dr. O'Dwyer, tracheotomy was the only surgical procedure for the relief of croup. The indication for the operation was the presence of laryngeal stenosis, and the physician had to determine only the degree of obstruction which made the operation imperative. Now, to him skilled in the performance of both operations, and confronted by dangerous laryngeal stenosis from croup, the question arises, shall intubation or tracheotomy be made?

The most recent systematic writer on croup, Dr. Geo. S. Gay, (Reference Handbook of the Medical Sciences, Article Croup,) says of the results of tracheotomy in America: "The statistics of results from the operative treatment of croup are very extensive, and those of late years, in America, are pretty uniform in their character. The formidable array given to the profession by the arduous labors of Mastin, Cohen, and many others, comprising over 11,000 cases as collated by Agnew, shows that from one-fourth to one-third of the cases of tracheotomized croup recover. Cohen's success has been remarkable. He reports 110 recoveries in 166 selected cases, most of them occurring in private practice. The experience of Jacobi, Cheever, Ripley, and many other American surgeons, while not as favorable as that of Cohen, is yet very satisfactory, about one-third of their cases terminating favorably." Dr. Gay adds his record of eighty six cases with twenty-nine recoveries, (33 per cent.), and the record of the Boston City Hospital 491 cases with 124 recoveries, (25 per cent.).¹

The most complete statistical record of intubation is that presented to the recent International Congress by Dr. F. E. Waxham, and gives 1,007 cases with 266 recoveries (26.07 per cent.).

From these figures it will be seen that the results up to the present time show intubation as a life-saving operation in croup to be inferior to tracheotomy. It is not improbable, however, that with fuller experience with intubation the instruments and the method of use may be so perfected as to give results equal to tracheotomy.

Some of the faults of the method are mechanical, and doubtless will be overcome; others I think are inherent to it and insurmountable.

The ease and rapidity with which intubation

can be performed, the ready consent that is usually given by parents, and the comparatively simple after-treatment, will continue to make it the favorite operation with many physicians. But leaving out of consideration these decided but sentimental advantages, and looking at the question only of the comparative life-saving power of the two operations, is it not possible that they can be made allies in the surgical therapeutics of croup? Is it not possible that in certain conditions, and in certain classes of cases each operation has special features that give it advantages over the other? In other words, can not the indications for tracheotomy be formulated anew, and with especial reference to its relation to intubation?

I shall not presume fully to indicate the distinct provinces of the two operations. Indeed, with our short experience with intubation, especially in its relation to tracheotomy, that is not possible; only the future accumulation of data will enable us to establish these points. I shall give simply the rules that I have framed for my own future guidance, and formed almost entirely from my own experience, and I offer them simply as a contribution to the settlement of the question.

My experience with the two operations is as follows:

To the time I commenced to perform intubation, about August 1, 1886, I had performed thirty-four tracheotomies with seventeen recoveries. Since then, I have made three primary operations, with one recovery, and five tracheotomies secondary to intubation with no recoveries.

To the present time, I have performed intubation nineteen times, with two recoveries. Two of the cases of intubation were infants 12 months old, and in the most unfavorable condition for operative interference. Three others were of such character that there was no hope of anything but temporary relief of the dyspnoea; two of them were suffering with grave septic diphtheria, and one had croup secondary to grave scarlatina. The remaining 14 cases averaged about the same as those on which I have performed tracheotomy.

In determining the comparative life-saving value of intubation, the three last cases, and perhaps the whole five, could very properly be omitted, as I should not have performed tracheotomy upon them. I cannot agree with some writers, who hold that dangerous stenosis of the larynx is an indication for tracheotomy regardless of the general condition of the patient. It seems hardly justifiable to subject a child suffering from almost certainly fatal septic diphtheria, to the additional pain of tracheotomy, merely to prolong its life a few hours. The performance of such operations accomplishes nothing for the patient, and often does irreparable injury to the operation itself. Unless I can offer some hope of recovery, I do not advise tracheotomy.

¹ Since writing the above I have learned that Dr. Gay was mistaken in giving American surgeons the credit of such a large percentage of recoveries. Some of the statistics he quotes were taken from European as well as American sources.

From a glance of this series of sixty-one cases, it will be seen that the results with tracheotomy approach those that have been obtained by the most successful operators, while with intubation they are very low.

For the sentimental reasons before mentioned, I have persisted in the O'Dwyer operation, hoping, as I gained larger experience, to show the good results obtained by some other operators, but with my long continued unfortunate results I do not feel justified in giving it, in the future, the preference to tracheotomy. Therefore I have formulated the indications for tracheotomy in its relation to intubation thus:

Intubation may be given the preference over tracheotomy:

1. In infants under the age of 18 or 20 months.

In infants of this tender age the results of intubation have been very good, and considering the difficulty of operation, and readiness with which these young patients succumb to the shock of severe cutting operations, the milder operative procedure is to be preferred.

2. In all cases in which, from the character of the symptoms, and the progress of the case, it is presumable that the exudate is limited to the larynx and the upper part of the trachea. My two successful cases were of this character. Neither coughed up membrane after the introduction of the tube, or had any difficulty in breathing, and each expelled the tube in a fit of coughing—one on the third, and the other on the fourth day.

3. Whenever from the hopeless character of the disease there is nothing to expect but to give relief from dyspnoea, and to make death comparatively easy.

Tracheotomy is to be preferred:

1. Whenever the pseudo-membrane is extensive.

The pseudo-membrane, even when expelled immediately after operation, almost always reforms, and necessitates the use of solvent substances in the trachea, either by the spray or by instillation. After intubation, local medication of trachea is almost impossible, while after tracheotomy, with the diseased trachea in sight and within easy reach, it can be done with perfect ease. Further, the expulsion of membrane and mucus, especially in an exhausted child, is very difficult after intubation, and the attendant can give no assistance; after tracheotomy the reverse is the case.

2. When, for any reason the operation is delayed until the patient is exhausted and deeply cyanotic, or is moribund. To give such patients a chance for recovery the relief of the dyspnoea must be perfect and immediate. The irritability of the reflex centres is so obtunded, and the muscular debility is so great, that the child does not make efficient efforts to clear its trachea.

The trachea and large bronchi are filled with soft membrane and mucus, and for several hours after the circulation is relieved the deeply congested mucous membrane pours forth a great quantity of secretion. So far as my observation goes, these children die in a few hours after intubation, worn out by imperfect respiration, and their ineffectual efforts to keep their tubes clear.

Case 1.—Boy, aged 2½ years. Moribund from severe dyspnoea of over twenty-four hours duration. Intubation 9 o'clock A.M. A little relief, but the tube filled up, and 11 o'clock A.M. the dyspnoea was again very severe. Tube removed and reinserted. No relief; death at 1 o'clock P.M.

Case 2.—Girl, aged 6 years. Moribund from eighteen hours of severe dyspnoea. Intubation at 1 o'clock P.M. A little relief, but all efforts failed to make the child clear the trachea. Tracheotomy at 2 o'clock P.M. with the O'Dwyer tube *in situ*. Expulsion of great mass of membrane and mucus with perfect resuscitation. Child died of pneumonia on the fourth day after the operation.

Case 3.—Child aged 2½ years. No membrane in the pharynx. Grave dyspnoea commenced at 5 o'clock A.M. Cyanotic at 9 o'clock A.M. Intubation. Respiration was fairly easy, but the child did not rally perfectly. The pulse was very weak. The tube commenced to fill in an hour, the child could not clear it, and died asphyxiated at 2 o'clock P.M.

Case 4.—Child, aged 4 years. She had been cyanotic for several hours. Intubation at 6 o'clock P.M. There was great relief of the dyspnoea, but the trachea was never perfectly clear of membrane. She began to fill up during the night and died eighteen hours after the operation.

Case 5.—Girl, aged 8 years. No membrane visible in the pharynx, but there was a little bad smelling discharge from the nose. She was cyanotic when I saw her. Intubation at 3 o'clock P.M. Expulsion of a large mass of membrane and relief from dyspnoea. The trachea began to fill in a few hours, and she died during the night.

All of these cases were seen in consultation. They were very similar in that all of them were dying from asphyxia alone. In all the pharynx was clear, and one only, *Case 5*, showed any constitutional signs of diphtheria. The condition of *Case 3*, was the most desperate of all, and she was relieved by a secondary tracheotomy and lived four days. In a number of tracheotomies that I have performed under equally desperate circumstances, the operation has never failed to give complete relief, and some of the children have recovered. But one child in my series of primary tracheotomies died within forty-eight hours after the operation. In these urgent cases intubation may be performed as a preliminary

measure to give time to properly prepare for tracheotomy. The temporary relief will give time, also, for a deliberate operation. The internal tube should be left in place and extracted when the trachea is opened. It greatly facilitates the operation.

3. In all cases in which the constitutional condition of the patient makes medication and feeding by the stomach imperative. The well-known difficulty of properly nourishing children after intubation may seriously compromise the result when we have to do with the grave debility of diphtheria.

It will not be possible, always, to definitely place cases of croup into one or another of the above classes. Many times the physician will be in doubt as to which operation is to be preferred. In deciding he should be guided by his relative success with the two operations. He who can obtain the average good results of intubation may try it before resorting to tracheotomy. The surgeon who has 30 per cent. or more of his cases of tracheotomy recover, should in justice to his patient select that operation. The utility of tracheotomy after intubation has been performed, and has failed to give relief, is a subject upon which there has been but limited observation. Five cases have come under my care.

Case 1.—Girl, aged 6 years. No membrane in pharynx. Intubation on the evening of the third day of the dyspnoea. She passed a quiet night, but the breathing was continually somewhat embarrassed, and at times when the tube was partially filled with secretion the dyspnoea was quite severe. The next morning the child's temperature was $102\frac{1}{2}^{\circ}$ and the pulse was 120. She breathed hard, was unable to clear the trachea, and was commencing to show signs of exhaustion. At 10 o'clock A.M., the tube was removed and replaced. A large piece of membrane was dislodged, after which she breathed easier. In an hour or two, however, the trachea again filled. She struggled hard for several hours before I was summoned. I saw her at 7 o'clock P.M., and immediately made a tracheotomy. She was perfectly relieved, and breathed easily until her death from exhaustion twelve hours later. Dr. W. P. Northup in a review of this case ascribes the death to pneumonia. I did not suspect it at the time.

Case 2.—Oct. 17, 1886. Girl, aged 9 years. Intubation at 10 o'clock P.M. Relief for eighteen hours. The trachea then began rapidly to fill. Tracheotomy at 4 o'clock P.M.; complete relief. Death on the third day from extension of the membrane to the bronchi.

Case 3.—Detailed as *Case 2*, of the cases illustrative of the effects of very late intubation.

Case 4.—April 9, 1887. Boy aged $2\frac{1}{2}$ years. Intubation at 9 o'clock P.M. Relief for three days when the membrane began to extend and to fill

up the trachea. Tracheotomy on the fourth day. Complete relief, but death three days later from bronchial croup.

Case 5.—December 29, 1887. Girl aged 5 years. Intubation at 5 o'clock P.M. Complete relief. The tube filled the next day when it was removed and cleaned and replaced. This gave relief for a short time only. Tracheotomy on the second day. This operation gave but little relief and the child died in a few hours.

These five cases very well show the superiority of tracheotomy over intubation in combating the condition which gives rise to the dyspnoea in croup. Tracheotomy not only will relieve all cases that intubation can, but it will do more. In four of the five cases intubation had failed to keep the respiratory tract free, and if left without further interference all undoubtedly would have died in a few hours. Tracheotomy gave them chances of life far beyond the power of intubation to do.

From the observation of these cases I should advise the performance of tracheotomy when intubation has failed to give relief, if the secondary dyspnoea supervenes within a few hours. The first deposit of pseudo-membrane in the trachea is generally thin and pus-like, and but loosely attached to the mucous membrane. It is a *croupous* membrane in the *anatomical* sense. It is easily expelled after tracheotomy, and this operation certainly offers some chance of recovery.

If the secondary dyspnoea be delayed for two or three days, it is then usually due to the deposits in, as well as upon, the mucous membrane. The pseudo-membrane is thick, tough and firmly adherent to the mucous membrane—it is *anatomical* diphtheria. With such a membrane filling the trachea and extending into the bronchi further operative interference is of no avail.

The surgical treatment of croup is often made useless by injudicious medical treatment before the operation. Medical treatment, is to a certain extent at least useful, and and it would not be wise to entirely neglect it, but so few cases of pseudo-membranous laryngitis recover under it alone, that it is best to consider it of secondary importance. Upon operative treatment only should any reliance be placed, and the medical therapeutic of the disease should be selected with especial reference to it. If recovery takes place without operation, it should be looked upon rather as a fortunate accident, than an anticipated result. The most frequent error made, is in the too persistent use of emetics. They are often given until profound exhaustion is produced, and when the obtunded reflex centers refuse longer to act, they are stored up in the stomach, and when reaction takes place, produce violent gastro-intestinal irritation. Think of such a preparation for a capital operation upon the subject of a serious acute disease! With such preparatory treatment

what would be the result of other grave operations? Of late years it has been fashionable in some localities to administer large doses of calomel to croup patients—one or two drachms or more in twenty-four hours. These large doses have been given with the idea of promptly producing the constitutional effects of mercury. If this condition has a favorable influence upon the course of the disease, and the testimony of many able physicians and my own experience make it probable, it would appear more reasonable and scientific to administer a readily soluble salt of mercury, or frequent small doses of calomel, so that the physician can control the amount of the drug taken into the circulation, something that cannot be done when large doses of calomel are given. I have heard it asserted that this enormous dosage never produces salivation or other serious results. My experience has been just the opposite. Of four cases seen in consultation, and which had been treated in this manner, one died before time was given for the mercury to produce any effects; two died after tracheotomy had been performed, one partially and the other wholly, I believe, from the effect of the distressing salivation and the violent enteric catarrh; and one was suffering so greatly from the toxic effects of the drug that I refused to perform tracheotomy.

Apparently trivial details of operation and after-treatment so greatly affect prognosis, that to be successful in tracheotomy the physician should be a perfect master of them. During and after tracheotomy death threatens from every quarter, and the surgeon must make the best of the few conditions over which he has control. It is a great advantage to be able to select the time for operation and the best results are obtained from operations not too long delayed. Still, while a child is living it is never too late to operate. A skillful operator will open the trachea by deliberate dissection in six or seven minutes and when time presses in much less time, so that, so long as respiratory efforts are being made it will not be too late. The grave condition late in croup is generally the effect of asphyxia alone, and with the admission of air into the lungs, resuscitation usually is rapid.

It would unduly prolong this paper to give the details of tracheotomy; a few general remarks, however, may not be out of place.

The operation should be performed with the greatest delicacy and with all the deliberation the time will permit. The cut to the trachea should be made with as little tearing and mutilation of the tissues as possible. I find it can be made most carefully and quickly by avoiding almost entirely the use of a director or other instrument except the scalpel. With the child's neck over a small round pillow the tissues are so stretched that as the successive passes of the knife divide them, the edges of the wound automatically re-

tract. In the operation above the isthmus, the only tissues that cause trouble and delay are the veins, and the use of retractors or a director, or even the retraction of the edges of the wound with the fingers, empty them of blood and make them invisible. With successive gentle passes of the knife point, avoiding the veins, distended and in plain sight, as they present, the connective tissue lying next to the trachea can be quickly reached. Difficulty may be experienced here, as in this tissue lie imbedded dilated branches of the superior thyroid vein, branches of the superior thyroid artery and sometimes the crico-thyroid. The cutting through this dangerous layer of tissues must be very carefully done and it is often well to separate it partly by tearing. The method of Boze is very safe.

In opening the trachea I prefer to make a short cut in it, and before withdrawing the knife gently to introduce a slender retractor with a long beak, then to withdraw the knife, introduce another retractor, and to enlarge the incision either way with a probe-pointed knife. With the edges of the tracheal incision well separated by the retractors, respiration can go on while the operator is clearing the trachea of mucus and membrane. There is usually no occasion for haste, and the canula can be carefully introduced when the trachea is clear. Many operators make the introduction of the tube the supreme moment of the operation, plunging it into the tracheal incision as soon as it is made, using the finger or some instrument as a guide. To this bungling method is due the inexcusable accidents of lodging the canula in the connective tissue alongside the trachea, and tearing the trachea, or its mucous membrane.

The canula should be so prepared as to cause the least irritation to the external wound, and the tracheal mucous membrane. This can be very well done by placing under the shoulder of the tube an apron of mackintosh cloth or oiled silk, and under that two or three layers of surgeon's lint or antiseptic gauze. This pad serves as a dressing to the wound, can be made fairly antiseptic, and protects it from the irritating contact of the metallic shoulder, and the secretion expelled from the tube. Another very important function it performs is to permit the easy play of the tube within the trachea during respiration, coughing and other efforts. The depth of the trachea from the skin varies much in different individuals, and as a result of inflammatory exudation. Variations in the thickness of this pad will give different lengths to the tube.

Pilcher, Cohen, Gay and other American writers have given to the profession such excellent articles upon the after-treatment of tracheotomy, that very little in addition can be said. The general indications to be filled, however, and the means at the physician's command to fill them,

cannot be too often repeated, as, in attention to these details above all others, lies the secret of success. After the operation the diseased mucous membrane of the trachea pours fourth a copious exudation of thick, tenacious mucus or pseudo-membrane. The inspired air quickly dries it and forms hard sticky masses that obstruct the newly made respiratory tract. These secretions must be kept fluid and the way clear for their expulsion. This is the chief indication in the after-treatment of tracheotomy. To accomplish it the essentials are:

To keep the apartment at a temperature of about 80° F., and the atmosphere loaded with moisture.

To administer remedies that are known to stimulate the tracheal and the bronchial mucous glands.

To keep over the tube a thick cravat of several folds of gauze or a piece of wet sponge, to further moisten and warm the in-going air.

To frequently change and clean the inner canula.

To use occasionally, in all cases, the steam-atomizer for twenty or thirty minutes at a time, and when the membrane forms fast and dries rapidly, to pour into the opening of the canula from one-half to three-fourths of the time a heavy steam spray of a mildly alkaline or solvent solution with the atomizer placed but a few inches from the canula.

Lastly, when, regardless of persistence in these measures, the trachea becomes obstructed, to remove the canula from the wound, and by instillation with a few drops of water, or with forceps, a feather or other instrument to search for and remove the obstructing mass, as would be necessary with any other foreign body.

Mr. Chairman, in bringing this very imperfect paper to a close, I wish to make a plea for more frequent operative interference in pseudo-membranous laryngitis. Whether it be intubation or tracheotomy that the physician may select is not a matter of importance so long as one is done. Without operative interference these children die, while with it a magnificent percentage recover. Every physician when confronted by a patient in the condition demanding tracheotomy, should have before his mind these eloquent words of Dr. Pilcher: "How long am I justified in deferring the application of a remedy which at once puts an end to grave sources of danger now present to my patient? The most approved methods of treatment have failed to arrest the course of the disease. There is a steady progression in its gravity. A possibility exists, however, that even at the last moment a favorable turn may take place and recovery follow. In all probability, nevertheless, it will steadily advance to a fatal termination. Shall I now give him the benefit of tracheotomy, with its unquestioned advantages,

or shall I wait yet longer? Each hour of waiting now will lessen rapidly the hopes which even tracheotomy affords. What is my duty to my patient? What other answer can there be than that *justice to my patient, justice to myself, fidelity to the profession I represent, all unite in demanding that now, early, before the development of conditions which will make any interference but a forlorn hope, tracheotomy should be done.*"

544 Jefferson Ave.

DOUBLE UTERUS AND VAGINA.

Read in the Section on Obstetrics at the Thirty-ninth Annual Meeting of the American Medical Association, Cincinnati, Ohio, May, 1888.

BY L. H. DUNNING, M.D.,
OF SOUTH BEND, IND.

Under the general title of double uterus and vagina I wish to consider the congenital malformations of the uterus described and classed by authors as uterus bipartitus, uterus unicornis, uterus bicornis, and uterus bilocularis, when one of these malformations is associated with a double vagina. My observation was directed to this subject something over a year ago, by having brought under my treatment a case of uterus bilocularis, associated with a double vagina. It was a case specifically described by Kussmaul under the name of uterus septus, vagina septa. Brief notes of my case are as follows:

Mrs. A., aged 37 years, married some months and never pregnant. Came to my office with her husband to consult me on account of something abnormal they had found about the genital organs. The following facts were elicited, viz.: Menstruation had begun when the patient was quite young, but had always been irregular and generally scanty. During the last two years they had been at times painful. Since marriage pregnancy had not occurred, but coition had not been painful and there were no symptoms pointing to serious uterine trouble.

Upon ocular inspection and digital examination the external genital organs were found normal and well developed. Upon separating the labia and looking into the *ostium vaginae* nothing abnormal would have been noticed upon casual examination. Upon close examination two vaginae were found, separated by a moderately thick septum extending from a groove between two cervixes to the introitus vagina. The right vagina was considerably larger than the left, and was undoubtedly the one used in coition. The finger entered this one readily, while the left one needed to be searched for. A cervix was found in each vagina and were normal in all respects except the left one was smaller, and both were shorter than normal. The probe entered the right uterine cavity 2 inches, and the left one 1½ inches. The points of the probe could not be made to meet and their

handles diverged slightly. No communication between the uterine cavities or vaginal pouches could be made out. By conjoined manipulation the uterus was found to be of normal size, except that the transverse of the body was greater, and there was a slight depression at the fundus, marking the division of the body of the uterus. That portion lying to the left of the depression was one-third smaller than that upon the right side.

About one month later the husband came to my office reporting that his wife had not had her menses, and that they thought her pregnant. Three months later she was seen by the writer and pregnancy found to exist. The labiæ and vaginæ had grown considerably, and were now of that livid hue sometimes indicative of pregnancy. The cervixes had enlarged and softened and the right side of the uterus had enlarged, so that it, with its contents, was as large as a normal pregnant uterus at the fourth month. The left side of the uterus had not correspondingly developed, it being apparently flattened out and lying like a molehill upon the left side of the impregnated uterus.

From this time on I saw the patient frequently, and became thoroughly convinced she would be able to effect delivery without operative interference. In due season labor came on in a normal manner. When I was called it had advanced well into the first stage. The right os was dilated to the size of a silver dollar, while the left one was nearly as large. The bag of waters protruded from the right os, and the foetal head was felt just within it. In another hour the right os was largely dilated with a large bag of water protruding from it. The left os was also large and I could determine the position of the foetal head through it as well as through its neighbor. It was found during this examination that there was a communication between the two sides half an inch above the internal os. The finger could be passed into one os through this opening and out the other os. The uterine septum had been torn and it was thought strongly probable that the head would tear the vaginal septum before it in its descent. This actually occurred. The second stage of labor was of four hours' duration and the pains were only moderately severe. At the vaginal outlet a band of the septum remained and was stretched antero-posteriorly over the centre of the foetal head and for a brief time retarded labor. By pushing the head back in the absence of pain this band could be pushed toward the left side, but not far enough to allow the passage of the head. Finally, after three or four pains, the band suddenly gave way, and the head was as suddenly born. The remainder of the child quickly followed, as also did the placenta. There was but little hæmorrhage or shock and the patient was at the end of labor in an excellent general condition. Strict antiseptic precautions were observed and at the end of two

weeks the patient had made a complete recovery.

When this case came under the writer's observation he began looking up the literature of the subject of double vagina and uterus, and found that contained in one language very meagre, and hardly satisfactory to one desiring to obtain a comprehensive knowledge of the subject. Todd's "Cyclopædia of Anatomy and Physiology" gives a brief but excellent anatomical description of congenital malformations of the uterus, but has little to say regarding double vagina. In the following works much valuable information may be found, viz.: Lusk's "Midwifery," Hart and Barbour's "Manual of Gynæcology," Fritsch's "Diseases of Women," Barnes' "Diseases of Women," and in Turner's articles in the *Edinburgh Medical Journal*, Feb., 1865, and May, 1866. The writer of this article has, by the invaluable aid of a physician having access to the Library of the Surgeon-General's office, collated and tabulated the histories of 97 cases of double uterus and vagina. Brief references to some of the facts thereby obtained may be of some interest. Before proceeding to this part of our subject a short anatomical description of the various forms of the malformations will not be inappropriate. Todd divides congenital malformations of the uterus into four groups.

1st. Uterus Bipartitus.—In this group the ducts of Müller are imperfectly developed, or undeveloped, and the result is a more or less complete absence of the uterus. The examples of complete absence of the uterus reported are believed by Todd to be cases in which the rudiments exist, sometimes with a fold of peritoneum lying behind the bladder. The concomitants of this condition are usually rudimentary ovaries and Fallopian tubes, a short vaginal cul-de-sac, a complete absence of the vagina, or in rare cases a complete vaginal pouch. In rare instances the ovaries will be found normal, and in still rarer instances there will be a pervious os communicating with the vagina, and the uterus, Fallopian tubes and ovaries sufficiently well developed to permit of conception and delivery. The presence of normal ovaries concomitant to rudimentary condition of the uterus may be understood when it is remembered that the "ovary is formed out of a separate portion of blastema of that from which the Wolffian bodies and excretive duct of the genitive apparatus are developed," so that the failure of growth of one does not necessarily involve a corresponding defect in the other. In this class is the greatest deviation from the normal development of the uterus.

2d. Uterus Unicornis, or the single-horned uterus, is the next in the order of the greatest departure from the normal in development. Here one uterine cornu retains the imperfect condition, while the other undergoes development, so that

¹ Todd's Cyclopædia of Anatomy and Physiology, vol. v, p. 678.

the uterus will consist of a developed and an undeveloped half, or there may be an entire absence of one cornu. Where a rudimentary horn is found this is then solid, or hollow, closely connected to its fellow or only joined to it by a pedicle, which may be either pervious or impervious. The ovary upon the side of the rudimentary horn may be absent, undeveloped, or normal. The Fallopian tube may be pervious or impervious. When the ovary is absent or imperfectly developed it is not unusual to find an absence of the kidney upon the corresponding side. In this group the vagina may be double or single. If it be double one side is likely to be rudimentary or much smaller than its fellow.

3d. Uterus Bicornis, or Two-horned Uterus.—This form of malformation is more frequently met with than either of the former ones. Here the uterine cornua generally develop symmetrically, yet with an imperfect junction of their lateral borders. There is in this class no evidence of plurality or duplicity of the uterus. The condition is due to defective development or failure to fuse of the lower extremities of the ducts of Müller, and a consequent conjunction of the two halves, as occurs in a normally developed organ. In some instances in this group there is no fusion whatever and there would appear to be two separate organs, and yet examination shows in every instance but a single ovary tube and round ligament for each horn, and thus is demonstrated the fact that the malformation is due to defective development, rather than to a duplicity of organs.

The uterus duplex bicornis and uterus didelphy's are subdivisions of this group, and they differ from each other chiefly in the degree of the separation of the cornua. In the latter the separation is complete, so that each cornu is capable of movement independently of the other. In this group, as a concomitant, the vagina may be single or double, as also may be the cervix and os. A rudimentary condition of one horn may exist.

4th. Uterus Bilocularis.—The slightest deviation from the normal will be found in this group. Here the uterine cornua are partially fused and may be equally or unequally developed. Usually a groove or fissure will mark the separation of the cornua, while the cavity is more or less completely separated into two parts by a septum. The vagina is also frequently divided into two parts by a septum. When this occurs there may be a cervix in each vaginal tube, or the septum may divide a single os into two parts. The writer's case was of this group, and in it the septum extended from the ostium vagina to the fundus of the uterus. Of the 97 cases the histories of which the writer has collected there were found examples of each one of the groups described. They were as follows :

Of uterus bipartitus	2 cases.
" unicornis	3 "

Of uterus bicornis	52 cases.
" bilocularis	23 "
Uterus single, os, neck and vagina double	2 "
Unclassified, except as double	15 "

Of these cases the vagina was double, *i.e.*, divided into two parts, in 77 instances ; single in 5 ; absent in 1 ; and not stated, but probably double, in 16 ; and there was atresia of one vagina in 6 cases. Some interesting and instructive facts relative to pregnancy were obtained. Of the 97 women having the malformation, 47 were married, and those who bore children whose marriages were questioned were 3, thus making in all 50 possible mothers. Of these, 42 women were pregnant 76 times. There were 42 natural deliveries, and 13 difficult labors. The means of relief in the difficult labors were forceps in 7 ; turned in 1 ; septum of the vagina cut in 4 ; and in 1 there was rupture of the uterus. The number of deaths at, or as a result of labor, was 4 ; 1 of convulsions ; 1 of rupture of the uterus ; 1 cause not stated ; and 1 of puerperal fever three weeks after delivery. Fourteen women miscarried 18 times.

It is interesting to know which one of the varieties of malformation we have described is most liable to become pregnant and what is the result in each case. Is the one-horned uterus less liable to become pregnant than the uterus separatus, and if pregnant is it more liable to result in miscarriage, or is labor more liable to be difficult or disastrous ? In our list no instance of a pregnant uterus bipartitus is found. Pregnancy occurred in uterus unicornis in 3 women ; in uterus bicornis in 21 women ; in 12 women having uterus bilocularis ; in 4 in which the uterus was single, but vagina double ; and in 2 of unclassified form. Of the cases of artificial delivery 6 occurred in uterus bicornis ; 2 in uterus bilocularis ; and 1 unclassified form.

These facts are what we would be led to expect when we remember the peculiarities of each class. The one-horned uterus is equally surrounded by muscular tissue, and will nearly or quite right its position in the pelvis before the end of the period of gestation. In uterus bicornis the deficiency in muscular tissue upon the inner aspect of the organ, or inability to rightly employ that tissue, either or both tend to make labor more difficult or protracted. There are two factors operative in removing the axis of the plane of the uterus from the axis of the plane of the vagina, *viz.* : The commissure (Todd) frequently placed between the separated horns of the uterus, the position and thickness of which determining the angle at which the diverging horns will meet in the grooved uterus, the action of the round ligament which being attached to one horn only of the uterus tends to keep it well outward in the process of development.

But what influence do the different forms of malformation have upon the ability of the preg-

nant woman to carry the foetus to full term? Our data is not sufficient to enable us to settle this question beyond controversy, yet the facts we find are quite suggestive.

Of the uterus duplex bicornis there were 6 pregnancies and 1 miscarriage; of the uterus bicornis, 5 pregnancies and 1 miscarriage; of uterus didelphys, 10 pregnancies and 5 miscarriages; of uterus bilocularis, 12 pregnancies and 6 miscarriages; of uterus unicornis, 3 pregnancies and no miscarriages. The large percentage of miscarriages in uterus bilocularis is due quite largely to the lodgment of the ovum in the decidua vera in the superior posterior portion of the uterine cavity near enough the septum so that as the placenta develops it spreads over upon the septum and hæmorrhage, or failure of growth frequently occurs, and miscarriage follows. The reason of the frequent abortions or miscarriages in uterus didelphys will, I believe, be found (a) in the unfavorable position the impregnated uterus gradually assumes as the period advances, which position interferes with its circulation, and (b) in the sympathetic excitement induced by the menstruation of its fellow.

What are the effects of the abnormalities under discussion upon menstruation? Menstruation is a function requiring for its normal performance a complex system of organs which must be perfectly formed, in perfect working order, and each bearing its proper relations to all others. Here we have abnormalities affecting a part or the whole of the organs of the menstrual system, and the abnormalities are those of development. The organs affected are chiefly the uterus and vagina, for it is not common to find errors in the formation of the ovaries in cases of double uterus and vagina even in the highest types of the malformation, for reasons already stated. To be more specific, there must be, in order to perfect menstruation, a normal ovary, a pervious tube, normal uterine mucosa, and a pervious os and vaginal tube. These are not always present and when they are not menstrual disturbances will arise.

The most disastrous of these disturbances we have found in our studies are hæmatomatra; the menstrual fluid being retained in the uterus in consequence of an impervious os, and hæmatocolpus resulting from atresia of one vagina. The former of these most frequently occurs in cases of uterus bicornis, but it is sometimes met with in a rudimentary horn which contains normal uterine mucosa and no communication between the developed and undeveloped horn. We found records of many cases in which menstruation was irregular, scanty, or painful, and some striking anomalies, some few of which may be mentioned. In one instance the patient gave birth to twins at six months from one uterus, menstruated regularly from it three times and then gave birth to a perfectly formed child from the other uterus. In

another instance menstruation occurred from both uteri and both became pregnant. Abortion occurred, and it was then ascertained that one uterus had been impregnated three months while the other only one month. It was also learned that both uteri may menstruate at the same time, or that they may alternate in the performance of the function. These facts all tend to emphasize the importance of the place the uterus occupies in the system of organs involved in the performance of the function of menstruation. If with a single uterus and two ovaries menstruation occurs normally every four weeks, and if with a double uterus, each half having a single ovary, the menstrual flow occurs from each every four weeks it would seem quite conclusive evidence that the uterus, and not the ovary, is the most important part of the menstrual system and, it would too, the writer thinks, tend to prove the cyclic nature of this functional manifestation, with the uterus as the center of the system.

What effect does the duplex condition of the vagina have upon the mature woman in respect to menstruation, married life, pregnancy, and delivery? Upon these points our text-books have little to say, but the writer has found in his investigations this is one of the most important parts of his study. Atresia of one or both vaginæ will lead to the formation of a hæmotocolpus. The suffering attending this pathological condition is great, while the dangers to life incident to operative procedures for its cure are also great. The subjects of duplex vagina are usually ignorant of its existence until after marriage, when they find coition painful or impossible. Occasionally a physician will be confronted during the progress of a difficult labor by the presence in the vagina of a firm septum, or he will recognize the existence of a double vagina in which there is a thick, firm, fleshy septum. In the list of cases we have studied (97 in all) we have found the septum described as complete, *i. e.*, extending from the os-tem vagina to the cervix uteri, in 72 instances. The following facts appear respecting the septum, *viz.*: The septum delayed labor in 2 cases, was cut away during labor in 3 cases, torn away in labor in 5, divided before labor in 1, divided for painful coition in 6, for relief of diseased conditions in 4, sloughed away after delivery in 1, and was divided for atresia of the vagina in 6 cases. In one of the patients having vaginal atresia of one side the foetus passed into the occluded vagina and had to be removed by incision.

It will be seen by this statement that the septum was an important factor in labor in 13 patients, or in more than one-third the women who were confined, as in only 36 of the child-bearing women was there a vaginal septum. It is pertinent to inquire what shall be our mode of procedure respecting this septum? If seen before pregnancy in the married woman it should be, if thick, firm

and unyielding, incised, excised, or severed by the galvano cautery. As a rule, the writer believes, it will be the best surgery to excise the septum and suture the edges of the mucous membrane, in order to avoid as nearly as possible resulting cicatricial tissue in the vagina. If an incision alone is used it should be crucial, in order that the incised surfaces may not come in contact and adhere. Should the patient be not seen until after pregnancy has occurred the operative procedure is best delayed until the fourth or fifth month.

There is nothing to contraindicate the severing of the septum during labor if it be found materially retarding labor. It is better to cut the septum than to allow it to be torn away as it was in the writer's case. Fortunately his inactivity did not entail upon his patient disaster or serious results, but he would not again hazard the risk of such an occurrence. The best operative means for the relief of hæmotocolpus has not yet been decided upon. Emmet boldly advocates free incision, immediate evacuation of the retained fluid and antiseptic irrigation of the cavity. The weight of authority seems to be against this method and in favor of puncturing the tumor and slowly draining off the retained fluid. Of the 3 cases in our list all were punctured; one died, one recovered, and in one the result is not stated, though it probably recovered. Similar results are shown in the three cases of hæmatomatra in the list. The writer has in his possession the histories of 20 cases of hæmatomatra treated by various methods and cannot forebear anticipating his paper by stating that by far the highest rate of recoveries is found in those instances in which a free incision was made and free drainage and irrigation employed.

Our conclusions are

1. Congenital malformations of the uterus and vagina are of more frequent occurrence than the experience of one man would lead him to suppose.

2. Of the forms of malformation of the uterus associated with double vagina the uterus bicornis is the most frequent, 51.5 per cent. belonging to this class.

3. Except in uterus bipartitus the fecundity of the woman having the malformation is not materially diminished.

4. The ratio of difficult labors is greater than in those having normal uteri. 24.1 per cent. were difficult labors; 28.5 per cent. being of uterus bicornis, and 16.66 per cent. being of uterus bilocularis.

5. The forms of malformation in which abortion or miscarriage is most liable are uterus didelphys and uterus bilocularis. In these 50 per cent. of the cases so resulted.

6. Both sides of the uterus may be pregnant at the same time and the fœtus in each in the same stage or different stages of development.

7. Disordered menstruation is of frequent occurrence. Atresia of one vagina will be found in about 8 per cent. of the cases. Stenosis of the cervix uteri is sometimes present.

8. Menstruation will take place if there be even a small amount of uterine mucosa and a normal ovary, and if there be not a free exit of the menstrual fluid hæmatomatra will result.

9. Menstruation may occur simultaneously from both uteri or they may alternate in the performance of this function. In the latter case it may appear every two weeks, and from alternate sides.

10. The two preceding conclusions show the important part the uterus plays in the performance of this function of female life.

SOME OBSERVATIONS, AFTER 1,000 OPERATIONS FOR HÆMORRHOIDS.

Read in the Section on Surgery, at the Thirty-ninth Annual Meeting of the American Medical Association, May, 1888.

BY JOSEPH M. MATHEWS, M.D.,

PROFESSOR OF PRINCIPLES AND PRACTICE OF SURGERY AND DISEASES OF THE RECTUM, KENTUCKY SCHOOL OF MEDICINE, LOUISVILLE.

Having for a number of years given special attention to diseases of the rectum, I have thought that this paper could be made more or less interesting by recording my individual experience in the operations looking to the relief of hæmorrhoids. I have based my conclusions from operations done upon patients taken indiscriminately from hospital, dispensary, and private practice. Believing that an individual experience is worth much in forming an estimate, I give mine for what it is worth.

Internal Hæmorrhoids.—This I believe to be the most common of all rectal affections, though Mr. Allingham believes fistula in ano to be. In making this estimate I rule out the diagnoses made by patients, who usually pronounce any and all affections of the rectum or anus to be piles.

Causes.—With deference to our French *confrères*, I am satisfied that constipation is the chiefest among the causes of hæmorrhoids. Nor can I subscribe to the belief that through the dissections made by Verneuil we find sufficient evidence in the peculiar distribution of the veins, and the course they take in the coats of the rectum, to disprove the theory that constipation, sedentary occupations, drastic purgatives, prolonged use of enemata, etc., can institute true hæmorrhoids. His idea that the superior hæmorrhoidal veins pass through "veritables boutonnières musculaires," and that these muscular button-holes have the power of contracting and causing such stasis and congestion in the superior hæmorrhoidal veins as to cause the "primum mobile" in the formation of internal piles, I do not believe. Upon this theory was dilatation of the two sphincter muscles suggested as a cure for internal hæmor-

rhoids. Whatever might have been its success in France, I am sure it has failed of its object in America. This failure I attribute to the unscientific basis upon which it was practiced. In a word, then, I believe hæmorrhoids to be veritable tumors, in the formation of which the arteries as well as the veins play a part. The mucous membrane of the rectum being movable, is everted at stool. Anything that impedes the return of blood will congest the part. This, sufficiently kept up, ends in the plastic deposit of inflammation constituting the material for the formation of piles. I quite agree with Verneuil, that the superior hæmorrhoidal veins are connected with the portal system, and in the main form internal hæmorrhoids, and that external piles are formed from the external and middle hæmorrhoidal which are not connected with the portal venous system, and hence the two venous systems, portal and general, are practically distinct at this point. This proposition is admitted, and yet we cannot admit the absolute separation of the portal and general venous systems. I have been thus explicit on this point from the fact that confusion has arisen over it.

Sex.—In my experience men are the oftenest affected with piles. This I account for on the basis that the portal circulation is in the male oftenest interfered with. This will outweigh the fact that childbearing and displacements of the uterus are pregnant causes of piles in females.

Age.—A number of authors cite cases of piles in infants. I have never witnessed the affection in children under 10 years of age. Old age is mentioned as most favorable to the disease. This has not been my observation. Old people frequently mention that during adult life they were so affected, but as the years grew apace, the piles disappeared. It is eminently a disease of middle life.

Classification.—The usual classification of piles is mystifying, to say the least. No anatomical difference can be drawn between the so-called venous and the arterial pile, and the commonly designated "capillary" pile frequently uncovers an artery of good calibre. The terms external and internal are quite sufficient for all practical purposes as applied to piles, for, as Mr. Erichsen says, "all internal piles should be tied, and all external piles should be cut off."

Dangers.—The only real danger from internal piles is hæmorrhage, and this can scarcely apply to any save the small incipient pile. The friction to which larger tumors are subjected causes such thickening of the mucous coat that bleeding, as a rule, is impossible. Sometimes large hæmorrhoids prolapse and slough, hence require surgical interference, but this could only occur from an indiscretion.

Operations. Injections of Hæmorrhoids.—For a number of years the injecting of hæmorrhoids

with carbolic acid seemed to be a favorite plan with many in the profession. Being a discovery of the itinerants, it soon found favor with the laity, more because of its secrecy than from any merit. After the remedy was exposed, the profession was able to give it a fair trial. Many, for a while, were inclined to look upon it with much favor, for the reason especially that it was easily practiced. After a few reported accidents, thoughtful men began the real study of the subject, the *modus operandi* of cure. After a sufficient length of time had elapsed for investigation, I took occasion to record my objections in an article read before the Kentucky Medical Society in 1878. In that paper the position was taken that the injecting of piles with carbolic acid was a dangerous procedure; that by the plan much inflammation was excited; the pain in the majority of cases very great and prolonged; that dangerous hæmorrhage was to be feared; that sloughing was the rule, hence ulceration, stricture, etc., might follow; that death might occur from hæmorrhage, embolism, or septic trouble; and that in no case could a radical cure be pronounced. After an elapse of ten years we find these predictions verified. Dr. Andrews, in his late work on "Diseases of the Rectum," p. 24, says: "The following accidents have been reported to us out of about 3,304 cases: Deaths, 13; embolism of liver, 8; sudden and dangerous prostration, 1; abscess of liver, 1; dangerous hæmorrhage, 10; permanent impotence, 1; stricture, 2; violent pain, 83; carbolic acid poisoning, 1; severe inflammation, 10; sloughing and other accidents, 35." Of course this was an indiscriminate collection and the half was not told. The quacks would not confess their bad results, hence most of this table was from accidents and results so plain that the profession ascertained them. Allingham reports thousands of cases by ligature without an untoward symptom and no death. Others are of the same good report. Kelsey, of New York, who a few years ago was inclined to advocate the injection plan, discountenances it now. Ball, of Dublin, who has just issued an admirable work on diseases of the rectum, only says in mention of it that the plan has been tried in America, but with poor success. The writer begs to say that what was said by him in 1878 he reaffirms in 1888. The remedy came in unawares, has been weighed in scientific scales and been found wanting. No authority to-day advocates its use.

Dilatation.—As has been suggested, after the views of Verneuil were promulgated, it was advised that dilatation of the sphincters be practiced for the cure of all internal piles. Such men as Gosselin, Dubrueil, Durch and others endorsed these views. The plan has been tried extensively in France and, the reports would indicate, with a moderate degree of success. In America it has proven a failure. The theory was wrong, hence the success bad. In the

early formation of piles, I have no doubt but that good could be accomplished by the plan, but after a pile is well formed I am sure it could not be cured by any such procedure.

Excision.—It is a little surprising to hear Allingham say that he regards excision as one of our best operations for internal piles. I think that an author should consider the audience he is addressing; and surely this sentence could result in much harm. To the surgeon accustomed to handling the rectum, the danger might not appear so great, yet to the many that might try this operation it would be fraught with much danger. It certainly can never become a popular method. I have had the internes try it at my hospital clinics, and in each case great difficulty was experienced in controlling hæmorrhage.

The Clamp and Cautery.—This is generally known as Mr. Henry Smith's operation. It finds great favor in the hands of Dr. Kelsey, of New York. It occurs to me that after a surgeon has had a certain amount of success with any given operation in surgery, he is loth to give it up. This certainly must apply to Mr. Smith, who is a great advocate of the clamp and cautery for the cure of internal piles. That this operation, compared to others, is cumbersome, cannot be gainsaid. That it is attended with much danger must be admitted. Any clamp is but a temporary safeguard, and if a break is made in the seared edges of the wound, bleeding must of necessity take place, and we all recognize the great danger of hæmorrhage into the rectum after an operation has been completed. The method has found but little favor in this country, and I am satisfied that, by comparison with the ligature, it will fall into disuse.

The Ligature.—Certainly, of all known methods, the ligature stands preëminent as an operation for internal hæmorrhoids. It has stood the test of years in the hands of the most eminent surgeons. To-day it is the most popular method. Easy of execution, free of danger, and rapid in its results, it can but command the attention of all who are interested in this operation. To the principle involved in the use of the ligature all are agreed, but the method of application is to a certain degree disputed. The method, as practiced by Mr. Allingham, is to dissect the hæmorrhoidal tumor away from its attachments, and then to surround the remainder, at its base, with a tight silk ligature. For the first few years in special practice I did the operation after this plan. I then modified it for the following reasons: 1. It was misleading to teach students after this fashion, because there was much danger in their dividing the artery which supplied the tumor. 2. There was more cutting than is necessary.

The modification consisted in running a delicate knife around the base of the pile, simply going through the integument. This saves any deep

cut and at the same time removes all superfluous skin, or external piles. Indeed, there are many cases of internal hæmorrhoids which require no cutting at all. This point is not sufficiently brought out in the books. I allude to the large internal piles which have no complication as mentioned here, viz.: superfluous flesh, or external piles. These require only to be brought in sight, ligated and returned into the bowel. Much stress is laid upon the degree of tightness that should be accorded the ligature; some saying apply it loosely, others advising it to be drawn tightly. I am sure that the tighter a ligature is drawn the quicker and more effectual will be the cure. A point is made in suggesting the kind of material to be used in the ligature. Many prefer silk. I am in the habit of using the stoutest linen thread, such as is used by saddlers or shoemakers. The twist of the silk, or other material, I am sure has nothing to do with it, as some seem to think it has. The kind of knot to be tied is spoken of, Mr. Allingham remarking that he ties the knot *three* times. Twice is quite sufficient, and the surgical knot has no advantages over the common hard knot. All internal piles existing should be ligated at the same sitting, and all returned into the rectum. The greatest care should be taken in cutting off the tumors after ligating. It is much best to leave the whole mass, rather than to have one ligature slip after returning the tumors into the bowel. The presence of the mass in the gut cannot result in any harm; the ligature is between it and the circulation. As a rule, then, it should not be cut off. A number who have written upon this subject say that the bowels should be confined for from five to seven days, and a light liquid diet enjoined. Certainly this is a mistake, for two reasons: 1. In this length of time the fæces will become hardened and impacted. 2. These patients generally require all the nourishment they can get. When following this advice I have had as much or more trouble result from impaction than from the original operation. My habit is to purge the patient the day of the operation, and to give an aperient on the second day after the operation, and each succeeding day thereafter until the patient is discharged. Consequently a full diet is prescribed if required. When operating under an anæsthetic I always divulse the sphincters, more especially if any cutting is done. This prevents the contracting of the muscles, hence obviates much pain when inflamed.

Anæsthetics.—It is often asked if the operation for internal hæmorrhoids can be done without the use of anæsthetics. If the sphincter must be divulsed because of the complication of fissure, ulceration, or what not; or if any cutting is to be done, then an anæsthetic is absolutely necessary. If internal hæmorrhoids exist without any such complication, and protrude well in response to the

bearing-down effort, then an anæsthetic is *not* necessary. It is often suggested that cocaine could be used with benefit in these operations. In the removal of external piles much benefit is derived from throwing the solution under the growth. In the operation for internal piles I have found it of little value.

Antiseptics.—Unfortunately, strict antisepsis cannot be practiced in these operations. Fortunately, it is not as necessary as when operating elsewhere. I am in the habit, however, in all these operations, of having strict surgical cleanliness as regards both the person and instruments. If any cutting is done the parts are dusted freely with iodoform, and the gauze of the same applied over the wound.

Results.—As the caption of this paper intimates, I have operated about one thousand times for hæmorrhoids by the ligature. I have never had to operate the second time upon the same patient for the affection. Have never had an unnatural contraction around the anus as the result of the operation, nor had ulceration or stricture to result. I have had in this time one case of tetanus, which I believe to have been superinduced by a debauch, the patient having been drunk for several days before the operation. The tumors protruded, strangulated and mortified, hence the operation. He recovered from the tetanus under the bromide treatment. Have had one case of secondary hæmorrhage occurring on the third day. The rectum was plugged and the bleeding stopped. Also one dangerous case of hæmorrhage which occurred one hour after operation was done, in consequence of the slipping of the ligature, the pile having been cut off. The patient was pulseless and cold when seen, but the artery was quickly secured and tied, and he made a good recovery. I have never had a single death result from the operation, and but few untoward symptoms.

INSANITY; SOME POINTS OF MEDICO-LEGAL INTEREST.

Read before the Section on Medical Jurisprudence at the Thirtieth Annual Meeting of the American Medical Association, at Cincinnati, May 9, 1888.

BY PHILIP ZENNER, A.M., M.D.,

OF CINCINNATI, LECTURER ON DISEASES OF THE NERVOUS SYSTEM IN THE MEDICAL COLLEGE OF OHIO.

The present status of Medical Jurisprudence is far from satisfactory, especially the position of the alienist physician in the courts of justice. His testimony often seems to be of little value. His opinion as to the nature of insanity and degrees of responsibility is often not admitted by the court. The medical jurisprudence of insanity will probably never be on an altogether satisfactory basis, until a due knowledge and appropriate feelings on the part of the community, lead to the enactment of proper measures in the

management of all defective classes, of which the insane is but a part.

Discussions of the subject in this organization, though it has no legislative power, may be productive of good because of the influence of a large body of scientific men, especially physicians, in making public sentiment.

The position of an expert on insanity before a jury, is exceedingly unsatisfactory to himself, and reflects but little credit upon him before the community. Conflicting evidence, expert testimony, equally emphatic on opposite sides, or undecided and conflicting on both sides, is the public spectacle usually presented. The radical fault is not that the testimony is naturally *ex parte* testimony, nor that those called upon to testify have frequently no special knowledge of insanity, though these are grave difficulties, but that the expert, however competent, personally has not the opportunity of making such observations as may assure a positive diagnosis. The important truth is not generally appreciated that special attainments are often equally or more necessary in order to know how and what observations to make as to judge from those observations what is the true diagnosis. In obscure cases untrained observers could not be relied upon to find hidden symptoms, more than they would be to point out the diagnostic tests in obscure cases of internal disease. The hypothetical cases put by the advocate are often worse than useless; but the brief personal examination often permitted to the physician may be equally misleading. There is but one satisfactory mode of arriving at a safe diagnosis in criminal cases, where the mental status is very obscure or doubtful. The individual should be held for a length of time, the duration varying according to the necessities of the case, in an asylum or other suitable institution, where he could be under constant and competent observation. But in order that such observations be reliable, the physicians in charge should be men of special attainments, an end that might be gained through their selection by representative medical bodies, rather than through political influence.

Another great difficulty in the medical jurisprudence of insanity, is the question of the proper test of the responsibility of the insane. There is a marked difference in the views of psychiatrists and those of the judiciary, the latter largely reflecting the sentiments of the community at large. The dictum of the court, that the proper test is the ability to distinguish right and wrong, cannot be accepted by experienced psychiatrists. Many of the insane have clear ideas on most subjects, and know full well what the world deems right and wrong, but, nevertheless, because they are dominated by delusions, or under the influence of powerful impulses, or merely on account of their perverted views and

perverted lives, should be judged differently from those of sound mind and dealt with more leniently. This view of the psychiatrist would save the family the odium of crime, but it especially arises from consideration for the insane subject himself. Compassion for human affliction as much as the sense of justice, prompts us to hold an individual irresponsible for his acts. The community at large entertains such feelings toward those who are in such an obtunded or confused mental state as to be practically bereft of intelligence. The psychiatrist, with his more intimate knowledge of insanity and active sympathy arising therefrom, entertains similar feelings towards all those whom mental disease has robbed of the ordinary modes of feeling, thinking, and acting, or who have not, in ordinary parlance, free will. I believe that most psychiatrists would agree that the legal test of responsibility should be the answer to the question, is the subject sane or insane. Such a test would be more readily acceptable if, at the same time that it settled the question of the legal responsibility of the individual, it did not therewith virtually dismiss him from further control, as is practically the case at present. On the contrary, such an insane subject should be completely at the disposal of the court. Matters of discipline, as well as the protection of society demand this. The knowledge of immunity may foster crime among the insane as well as those of a sound mind, while due punishment tends to restrain it. But a special aim must be to protect society from the acts of such irresponsible persons. The ill will with which the community views condoning the acts of the criminal insane, is doubtless partly due to the fear that society may suffer again at the hands of the same individuals, and too often the verdict "insane" virtually sets such people free in society. I could mention an instance of this kind in which I was unfortunately the means of having the prisoner pronounced insane. I say unfortunately, because, from prudential considerations, it would have been much better that the individual should be in the penitentiary than allowed full freedom. Such difficulties could be avoided and proper measures in each case be instituted if, when a verdict of insanity were rendered, the disposal of the case would be left to the discretion of the court. The latter, with the assistance of proper medical counsel, should then order the patient to be retained in an asylum temporarily or permanently, or even inflict degrees of punishment, according to the nature and circumstances of the case.

Questions of insanity in court, indeed, the whole subject of the disposal of the insane, would become a much simpler matter if proper views were held, and proper measures taken, as to the treatment of all defective classes. A large part of the defective class is composed of crim-

inals, at least a large part of the crime class is naturally defective. Their history shows this. It is only in recent years that the mental status of criminals has been made the subject of special study, and more philosophical views entertained as to the nature of crime. In many instances they are found to be possessed of impaired nervous systems and abnormal mental traits. The anatomical investigations of this subject are yet in their infancy. The view that there is a certain type of criminal brain must be looked on as chimerical. But various anatomical defects, or abnormal configurations of the skull have not infrequently been found, conditions which seem to ally such brains with those of degenerative forms of insanity, especially paranoia. Of more value are the clinical studies of the crime class. A valuable contribution to this subject has recently been made by Dr. Robinson,¹ physician to the Eastern State Penitentiary of Pennsylvania. His observations are to the effect that a large percentage of such individuals belongs to families of criminals, in which, at the same time, insanity or other nervous diseases are found, and that the criminals themselves present various abnormalities about the skull, are often the subjects of nervous diseases, and are already, or become, insane. In perpetrating criminal acts, they often are merely acting according to the depraved instincts of their nature rather than from necessity or greed. Such facts indicate the presence of abnormal nervous systems, or that the individuals belong to the defective classes of society. This must be accepted as true not of all, but of a large part of the crime class, and its general recognition is important, because it would tend to create the proper feelings toward this class and lead to their suitable treatment. The insane were formerly believed to be possessed of evil spirits, and subjected to scourging and other brutal treatment. When it became known that they were the subjects of disease, they began to be treated with the care and leniency due to human affliction, with the result of ameliorating their condition and assisting their restoration to health, thereby benefiting society at large, as well as adding incalculably to the well being of the afflicted. Similarly a correct idea of the crime class should lead to changes in their manner of treatment to the benefit of both themselves and society. The satisfaction of revengeful feelings, the idea of punishment, traces of a barbarous age, are still, to a large extent, elements in the treatment of crime. There should be but two considerations in its treatment, the protection of society, and the improvement of the criminal. The more nearly these ends are accomplished the more nearly perfect are the methods of treatment. But the present method of disposal of criminals does not tend to the accomplishment of these ends.

¹ Journal of Nervous and Mental Diseases, vol. xiv, page 281.

The criminal is for a short time secluded, and to that extent society is protected, but this period of seclusion is comparatively short, and when he is again free, he is usually more dangerous to society than before his punishment. His character is hardened. He is morally worse. Therefore, both the criminal and society are injured by his temporary punishment. A special injury from that punishment must not be over-looked. Many crimes are the result of passionate impulse or great temptation, while their perpetrators are not persons of criminal character. There is no reason why such individuals might not again become good citizens, but their future life is ruined, and they may even be driven to crime, on account of their subsequent reception by society. When their period of punishment is over the reputation of the prison clings to them, and deprives them of the common opportunities of making an honest and honorable livelihood.

What remedy can be suggested for the removal of the evil effects of the present treatment of crime? The method of treatment I have to propose, while it can only be vaguely outlined, points out, in my opinion, the direction in which changes should be made. First, I believe the guiding principle in treatment should be this, that punishment must be adjusted, not to the crime, but to the criminal, to the character of the individual, rather than to his deeds. As far as possible criminals should be divided into two classes. The first comprises those in whom the criminal act is an outgrowth, not of character, but of circumstances, the result of great temptations, blinding passion, etc. If such a distinction was clearly made, the members of this class would probably be received with such a degree of trust by society that their future need not be altogether wrecked. Probably they would carry with them only the reputation attached to their acts, and not an additional prison taint. As this class has no constitutional tendency to vice, there would not be the danger of their breeding the criminal class, nor any special future danger from themselves.

The second class includes those of criminal character. They are, and always will be, a danger to society. In addition to this, as they breed their own kind they are constantly adding to the crime class. From these ills, the danger from the criminals themselves, and the multiplication of the crime class, society should be, as far as possible, protected. Such criminals should be permanently secluded, but inasmuch as they belong to the naturally defective classes, and therefore are deserving of commiseration, their seclusion should be the least possibly painful, consistent with our great aims, protection of society, diminution of the crime class, and their own support. The best means to accomplish these ends must be learned from experience,

especially from the wise observations of those conversant with penology. That many difficulties must arise in their application, the oft times difficulty of distinguishing the class to which the criminal belongs, the fact that the two classes merge into one another, and that a large number of criminals cannot be properly arrayed with either of them, need not in any way affect the great principles involved, or interfere with their practical application. Many adjustments would be necessary which would naturally grow out of experience.

A CASE OF NECROSIS OF THE MASTOID CELLS AND THE ENTIRE LABYRINTH OF THE OTHER SIDE, WITH PARALYSIS OF THE FACIAL NERVE,

FOLLOWED BY PARTIAL RECOVERY OF HEARING.

Read at the Congress of Otolaryngology, Brussels, September 10, 1888.

BY LAURENCE TURNBULL, M.D., PH.G.,
AUROLOGICAL SURGEON TO THE JEFFERSON MEDICAL COLLEGE HOSPITAL,
PHILADELPHIA, PENN.

In most of the cases of purulent disease of the ear extending from the middle ear to the brain, the upper bony wall (roof) of the tympanic cavity is the part usually affected, and by this route the disease is carried direct to the cerebrum or cerebellum; transmission may also occur through the blood-vessels and other sources. Another and more rare method of tissue conveyance of ear disease to the brain, is by way of the labyrinth through the inner wall of the tympanum and round window. The base of the stapes again, with its delicate ligaments, forms the only septum between the tympanum and vestibule, and when suppuration takes place in the labyrinth, the disease advances through the cribriform floor of the internal auditory meatus to the auditory nerve, and thence to the base of the brain and medulla oblongata. In other cases, purulent matter is formed beneath the arachnoid, over the whole surface of the brain, or an abscess may develop between the arachnoid, the pia mater, or by pressure in the brain substance. In some rare cases the disease extends a considerable distance down the medulla spinalis.

When destruction of the bone has extended in the direction of the posterior cranial fossa, abscesses form in the cerebellum.

In the case we are about to relate the whole labyrinth became necrosed.

Mary T., æt. 9 years, a girl with dark eyes and hair, of delicate constitution, was admitted for otorrhœa as an outdoor patient of the Jefferson Medical College Hospital, July, 1882. The disease succeeded a severe attack of scarlet fever in the early part of the year. After recovery fistulous openings showed themselves over the upper part of the mastoid cells of the right side. These

openings were enlarged and a mass of dead bone removed under antiseptic treatment.¹

The opening healed under careful treatment, nourishing diet, and alteratives of bark and iodide of iron. She absented herself without consultation, and nothing was heard of her until December, 1886, when she returned with a profuse left-sided otorrhœa, facial paralysis, and deafness. From the mother's account she had suffered from an attack of diphtheria, with inflammation of the middle ear with extension, evidently, into the labyrinth, also involving the facial nerve (within the Fallopian canal), with loss of sight, hearing and locomotion. This attack terminated, not in death, as is the usual result, but in an extensive abscess involving the middle ear and side of the face, accompanied with profuse bloody discharges, the lumen of the auditory canal being filled with a mass of polypoid granulations. The girl was admitted into the hospital, and the following operation performed.

She was etherized, and by means of Wilde's modified snare the entire polypoid mass was removed. This was followed by a profuse discharge of dark venous blood, which was checked by syringing with ice-water, and then the meatus was packed with tannic acid, camphor and iodoform. After this operation she was kept in bed for a few days until she recovered from its effects.

On December 3 she was again put under the influence of ether, and on introducing a probe it was found that the external auditory (bony) meatus and temporal bone of the left ear were necrosed; there was also ulceration and sloughing of the whole cartilaginous canal. A strong pair of bone forceps were carefully introduced, and considerable force employed so as to bring the diseased portion of bone to the surface; but it was not considered safe to remove it at that time. It was so large it was feared it would lacerate and injure the parts.

She was again taken to the ward, after stopping the flow of blood with antiseptic cotton. The resident physician of the hospital was directed to keep the parts well packed, using powdered boric acid with absorbent cotton; and for the removal of any offensive odor to use a solution of permanganate of potassium. After ten days of this treatment, the dead bone became so loose that it was removed through the enlarged meatus without pain or any symptoms of cerebral disturbance.

The patient was kept in the ward for six weeks, until all discharge had ceased. She was then placed upon large doses of iodide of potassium and tonics, strychnia, etc., with the use of the galvanic battery for the facial paralysis. She became well and strong, able to talk more plainly, and to use her feet and limbs. She could hear loud conversation in the right ear, but there was no improvement in the facial paralysis, nor diminution of the deafness in the left ear.

After her discharge, the mother was given a card to Dr. G. Betton Massey, a distinguished electro-therapeutist, who treated her for some time, but without much benefit, for the paralysis. Time has restored in part the connection of the nerve. Such cases as this have been reported by Dr. Friedrich Bezold² and others.

Description of the Specimen.—From the density of structure, weight, and shape of the portion of bone removed, we felt convinced that it was almost the whole of the petrous portion of the temporal bone. This opinion was confirmed by a more careful examination and section by Dr. Morris Longstreth, pathologist to the hospital. The following is his report:

Report on Sequestrum from the Ear.—The sequestrum, embracing the whole labyrinth and Fallopian canal, measures in its long axis nearly an inch ($1\frac{5}{8}$ inch), and its transverse measurement on section surface is slightly over half an inch ($\frac{1}{2}$ inch). It weighs 36 grs. Its surface is rough, jagged, and eroded by the necrotic process, except at one portion posterior to the internal meatus, which appears dense, white and smooth, like the inner skull surface covered by the dura mater; on this part is a shallow furrow like those provided for the folds of this membrane, or for a blood-vessel or sinus. The opposite surface shows above the "fenestra ovalis" and below it the "fenestra rotunda," the latter opening broken and irregular.

The fragment of bone is penetrated by several foramina—one large one towards the tapering end, and two smaller ones near the same end, but on the opposite aspect; these two are the entrance and exit of a canal (referred to before) through the bone tissue. A section through the long axis of the fragment, which on the cut surface shows itself to be very dense, reveals a half dozen cells, excavations which intercommunicate and are connected with the external foramina already spoken of.

In the interior was found the vestibule with its fossæ, the cochlea, modiolus and lamina spiralis, with the semicircular canals broken off near their junction with the vestibule.

May 5, 1888. The present condition of the patient is as follows: She is in perfect health, well and strong, being able to hear a twenty inch watch one inch on the right side, the right being the ear from which the portion of necrosed mastoid was removed.

There has been no discharge from either ear since the removal of the diseased bone. The C-3 tuning-fork was heard (felt) in the air in front of both ears, but as a musical sound heard only in the right ear. Her articulation is at times more or less imperfect, but she is able to talk, and repeat the German alphabet and give all the letters their proper sound. She attends a German school

¹ See author's "Clinical Manual of Diseases of the Ear," p. 361, 1887.

² "Necrosis of the Labyrinth and Paralysis of the Facial Nerve." Archives of Otolaryngology, vol. xvi, No. 4.

with hearing children. The facial paralysis remains the same. The experiment of Valsalva is felt in both ears.

The meatus from which the sequestrum of the left labyrinth was removed is twice the size of the normal, and cicatricial tissue is seen on its sides. In the other there is a small narrow meatus with a cicatricial pseudo-membrana tympani.

This is a remarkable case, in that, after the most severe symptoms involving the brain, accompanied with paralysis of the face, arms, limbs, and total deafness on one side, and such a copious discharge from the ears, there should be recovery to such an extent that the patient has no otorrhœa, is able to hear and converse, and so take her place at home without having to be sent to an asylum.

The specimens, photograph and cuts were presented to members of the Section for inspection.

M. HARTMAN, of Berlin, has treated a case of necrosis, with exfoliation of the labyrinth, and although the tuning-fork was heard on that side, the patient was deaf to the sound of the voice.

M. POLITZER gave an analogous case, that of M. Burkhardt-Meriau at the Congress of Bâle, which seemed to indicate that the sound could be directly perceived by the acoustic nerve.

DR. BARR, of Glasgow, showed the sequestration of the osseous labyrinth of a child ten years of age, attacked after several years of otorrhœa, following scarlatina. The patient had a facial paralysis, but was not affected with dizziness, although the semicircular canals were eliminated.

M. GELÉE: I ask my confrères if they think anyone can hear without ears, or if it would not be better to suppose that these eliminated sequestrations did not comprise the entire ear. For my part I prefer to believe that there is yet a portion of the labyrinth which perceives the sound of the tuning-fork rather than to suppose that the facts exist contrary to physiology.

THE THERAPEUTIC ACTION OF SOME OF THE MINERAL WATERS OF THE UNITED STATES UPON MA- LARIAL DISEASES;

WITH RULES FOR THEIR USE.

Read before the American Climatological Association at the Congress of American Physicians and Surgeons, Sept. 19, 1888.

BY W. C. VAN BIBBER, M.D.,

OF BALTIMORE, MD.

The effect of bad air upon the human system is shown in various ways, the differences depending upon the particular kind of air which causes the diseased conditions. Salubrious situations on the earth are known and recognized mainly from certain characteristics of the human inhabitants. It is true that other air breathing animals are in-

juriously affected by bad air, but this comparative study is not within the scope of the present paper.

Many of the changes in health, and grades in constitution produced by climate upon man are well known, and those peculiarities of disease existing in the inhabitants of different atmospheric planes have not escaped observation. The practicing physician and climatologist will do well to study the effects of hills and mountains upon the human organism, for they exercise influences not to be accounted for by the chemical analysis of the air. By far the greatest number, as well as the most serious diseases, produced by the quality of the air alone, are found to originate in the lower strata of the air, that is, at an elevation but little above the level of the sea. It is true most of the inhabitants of the earth live in these lower strata, because most of the great cities of the world are built upon navigable waters, and the most fertile lands are found in alluvial formations.

It is believed that the plane of the atmosphere three hundred and fifty feet above tide water is for the most part free from that mysterious something which produces ague and fever. A few noteworthy exceptions may be found to this law, but the planes of the atmosphere, from the tide level, to a height of ten thousand feet, have already been studied as to the production of certain diseases, and to the curing of others, and the work is still going on. This is one of the chief problems of the science of Climatology; and one result of these observations shows that certain symptoms and individual appearances, accompanied by constant pathological changes, are found with us, only as a rule, upon the ocean slopes and large river bottoms, and seem to be identified with this particular atmospheric plane.

To state the matter more precisely, we may say that, if a thousand men should be selected and taken from our sea-board swamps and river bottoms, below the thirtieth parallel of latitude, and placed side by side with a thousand men selected from a plane of the atmosphere over three hundred and fifty feet above tide water, north of the 30th parallel of latitude, the one set of men, can be distinguished from the other set, by the practicing physician, both whilst the men are living, as well as by an examination of the organs of the cadavers. Again, it is believed, that, should the men from the hills and those from the swamps change abodes for a few years, corresponding changes would take place in their physical peculiarities and outward appearance. These peculiar individual changes are wrought in a gradual manner by time, and, until recently, it seemed to be by an undetected hand; yet the changes are none the less certain and well marked.

It is the changes which will take place in the thousand men transferred from the hills to the swamps which will now engage our attention.

These changes steal along in the human system, for a time possibly without noticeable manifestation; until finally, a culmination takes place, and a chill, a fever and a sweat ensue in their proper courses. Then what was latent before soon becomes active, and the marked individual appearances begin to manifest themselves. These are externally, a sallow and stretched skin, muddy colored conjunctive, dry hair, dry and brittle nails, emaciation, a stooped curved and shrunken figure, and a slow crumbling of the teeth. The peculiar sensations or feelings which accompany these external appearances, are a gradual loss of strength and vigor, a desire to recline and rest, torpor of mind as well as of body. As mental effects we notice loss of ambition, indecision, procrastination, superstition, a craving for stimulants, with a continuous belief in "biliousness." These symptoms come on slowly and may continue for years without relief, because they seldom, or never, of themselves produce death, though their effects are serious and far-reaching; and, as will be seen hereafter, the three largest and most important organs of the body are so altered in texture and function, that there is, comparatively speaking, but little of the physiological man left. It is no wonder therefore that there should exist under these circumstances a predisposition to pneumonia or other fatal affections. So that, when from some intercurrent disease or from accident, death does ensue, the liver is found enlarged, generally softened, but sometimes indurated, and always changed in color, being filled with a black substance called "pigment." The spleen is likewise enlarged, softened and changed in color. The marrow of the bones is also altered in color and consistence; and a peculiar crescent shaped micro-organism has been found in, and around the red blood corpuscles, which is thus described, in a letter to me by Surgeon George H. Sternberg, U. S. A. He says:

"In response to your questions I would say that the parasite discovered by Laveran in the blood of malarial fever patients presents itself in various forms. Some in the interior of the red corpuscles, amœboid and segmenting forms, and some free in the serum, crescentic and flagellate forms. That these forms represent different stages in the life-history of the same micro-organism is inferred from the fact that pigment granules are found in all of them, and also from their association in the blood of malarial fever patients and from the fact that they have not been observed under other circumstances.

These facts also give strong support to the view, that the parasite in question bears an etiological relation to malarial manifestations. The rapid destruction of red corpuscles during a malarial paroxysm, and the accumulation of dark pigment granules derived from the blood especially in the liver and spleen as the result of re-

peated attacks, is quite in accord with the observations of Laveran, Richard, Marchiafava Celli, Golgi, Councilman, Osler, and others relating to this interesting hæmatozoon."

The disease now under consideration, was anciently called malaria because it was universally believed to be due to unwholesome air. At present there is a question whether it comes into the system from the air, or through the water, in those situations where it is found; but there can be no question as to the identity of the affection; and this is the disease which will be considered in this paper.

It is surely a high office for the physician to study additional means of relief for those piteous sufferers from this terrible malady, and no more useful aim can engage the attention of this Society than to unite, in its collected wisdom, during this discussion, in an endeavor to ameliorate such suffering as is familiar to you all. The most important advance in this direction, was the introduction into Europe of the cinchona bark about the middle of the seventeenth century, and its properties as a febrifuge were soon widely recognized. Numerous theories have been advanced as to the mode of operation of this remarkable remedy, and still the problem remains unsolved; perhaps only to find a solution when we shall thoroughly understand the diseased conditions for the relief of which it is employed. The three things which we may take as definitely settled, are that the "Jesuits' powder" is beneficial in these fevers, that it does not always cure them; and that we neither know why it succeeds nor why it fails. The immense number now suffering from both the acute and chronic forms of this kind of malaria, notwithstanding the most liberal use of the specific remedy, is sufficient to prove conclusively that it has not an absolutely curative effect by itself.

The purpose of this paper is to suggest certain supplementary or auxiliary remedial agents in the treatment of these diseases; and these are found among the mineral waters of the United States. For more than eighty years the waters of the Greenbrier White Sulphur Springs, in Greenbrier County, Virginia, have had a high reputation for the cure of malarial diseases. The situation of the spring is in a beautiful mountain valley, twelve hundred feet above tide level. The medicinal virtue of the water is supposed to reside both in its solid and gaseous contents. Bad cases of the kind of malaria which has been described, are to be found visiting this spring every summer for the benefit of its water; and a large proportion of these patients come from the cotton and rice plantations of the sea-board; some from the valley of the Mississippi river and its tributaries; and others from the valleys of the rivers which empty into the Gulf of Mexico. I first visited this spring as a physician in 1851.

Since that time I have had opportunities to study and observe the effect of this water upon the kind of malaria which has been described; and my observations have led me to adopt a regular system for its use.

The plans of cure which I shall recommend have been tested upon many patients and with generally good results. It often happens that those wishing to be benefited cannot remain at the spring longer than from two to four weeks; and to suit this necessity, the plans have been called the two and the four weeks plans.

That for two weeks consists in drinking as much of the water, early in the morning, as is necessary to sensibly affect both the bowels and the kidneys—enough to give one or two loose watery movements from the bowels, and a free discharge from the kidneys. For this purpose an average person will require from two to four glasses of the water early in the morning. These should be taken whilst the patient is in active exercise in the open air, and two hours should elapse after drinking the last glass of water before taking breakfast. At noon take a warm bath of the sulphur water, temperature 94° to 98° F. and remain in the bath from fifteen to twenty minutes. Whilst in the bath drink two or three glasses of the sulphur water. The time of the bath should be arranged so as to have dinner or lunch soon after leaving it: say about two o'clock, which is the usual dinner hour at the hotel. After this drink two glasses of the water at five o'clock P.M.; and two before retiring at night. Wash in the sulphur water morning and night; and exercise freely during the day by walking in the mountains. This two weeks systematic course has such a decided alterative action that few persons can safely carry it further than the time specified.

In the four weeks course the bath is ordered every other day, and the amount of the water to be taken may be proportionately moderated. The four weeks course should always be preferred when time can be given for this purpose. The object of this treatment is to produce a continuous acceleration in the action of both bowels and kidneys, and to increase the activity of the skin. These three objects are undoubtedly accomplished, and during the active course of treatment a good indication of its future success is found in the increased vigor and improved appetite; elevation of spirits, with a feeling of lightness of the body, and buoyancy of the mind, which are most agreeable. One of the peculiarities of this water when drunk pure from the fountain, is to elevate the spirits with a sensation not unlike that produced by champagne. It causes a slight feeling of dizziness and an excitement of the brain. It may be this which gives a charm to the place, and a lustre to the ball-room which is not seen elsewhere. But it should always be used with refer-

ence to individual idiosyncrasies, either pure from the fountain, or "staled" by the evaporation of its gas according to the valuable rules given by Dr. J. J. Mooreman, who was for more than thirty-five years the resident physician there.

The other springs, with the waters of which I have had nearly as long an experience in chronic malarial troubles, are the Saratoga Springs, in Saratoga County, New York. There are now more than twenty-one springs opened at this famous place, each one of which has a different chemical analysis. My observations have been more particularly confined to the Congress, the Hathorn, the Hambleton and Washington Springs as drinking waters, and to the Putnam, the White Sulphur, and the Red Springs as bathing and washing waters. From these I have made up a definite course of treatment, which I advise for two weeks and four weeks, similar to the courses already given for the Greenbriar White Sulphur water, and which, I think, has many advantages.

During the first week of the two weeks course, as much of the water of the Congress Spring should be taken, early in the morning, combined with active exercise, as will produce a decided effect upon the bowels and kidneys. An average person will require from two to four glasses of this water, and the last glass should be taken about an hour and a half before taking breakfast. During the second week of this course the Hathorn Spring should be used. Take each day at noon a bath of the Putnam or White Sulphur water, at a temperature of 94° to 98° F., and remain in the bath from fifteen to twenty minutes, drinking whilst in the bath, one or two pints of the Hambleton Spring water. At 5 P.M. take a wineglassful of the Washington Spring water, not more; and at 6 and 10 P.M. take one or two glasses from the Congress or Hathorn Springs. Wash night and morning in the water of the Red Spring.

This gives a definite course of treatment, the object of which is to produce an alterative effect, and to rapidly change the molecular structure of the body. Few individuals can continue such a course of these waters for a longer period than two weeks. In the four weeks course, which is always to be preferred if it is possible, the bath is to be taken every other day and the amount of the waters taken each day to be proportionately diminished.

In this course of treatment, by the water of either of these springs, the activities of the body are increased in every department, the bowels, kidneys, skin, liver, stomach, mind and spirits are all safely and agreeably stimulated. It is a full occupation of his time for a patient to undergo this treatment. To most persons it is a delight to experience the sensations resulting from it. The entire body seems to be renewed, the patient feels confident that the change will be last-

ing. It is a safe treatment; it is systematized and may be changed to suit individual cases. If this system is carried out it may be of service in preventing that blind bathing and drinking which our physicians find so injurious at all the springs in this country and which is in strong contrast with the practice at similar health resorts in Europe.

Having pointed out two springs which are salutary in malarial troubles, and having given those rules for the use of their waters which I have found most beneficial, I might here let the subject rest; but the disease of which we are treating is such a remarkable one, its literature is so large, its prevalence so widespread, its theories so interesting, that I trust I may be permitted, in closing, to say a few words concerning the *modus operandi*, or the manner by which the beneficial effects of the proposed system are produced.

Until about eight years ago everything concerning the cause of intermittent or remittent fever was obscure, and everything concerning the manner of its cure was a matter of theory and conjecture. Now a step has been taken in advance which will increase the interest attached to its treatment. Students in Europe; at the Johns Hopkins University; in Philadelphia, and elsewhere in this country, have made public the results of study and experiment, which bring the whole subject into a new phase; replace fancies by facts, and introduce a new method of treatment. To bring this out clearly, I will place side by side the two explanations of the manner of cure, in order to contrast the old teaching with the new:

The old explanation.—"By the use of the waters as advised, all the outlets of the body have been opened, and in this way the diseased particles have been removed. What particular path they took to get out of the system is a matter of conjecture; but the result of the treatment is sufficient to prove the fact that they were eliminated by some means or other."

The new demonstration would read in this way:—"The hæmatozoon which controls the disease has been found, and a study of its movements will alone reveal the truth. The number of red blood-corpuscles which have been damaged in any particular case can be told by actual count; and the restoration of healthy red blood-corpuscles can be determined in the same way. Under certain favorable circumstances the healthy red blood-corpuscles are rapidly formed, and when they are sufficiently abundant and vigorous, they dominate the system, resisting both the reception and encroachments of the disease. Those globules that were formed at the two springs, both of which are situated at elevations above the usual melanæmic line, were produced under different and favorable circumstances of air, food and water. If, during a certain system of treatment, the blood

be rapidly brought from a condition of disease to one of comparative health, we may legitimately infer that those globules which have been formed in the progress of the treatment, are of a healthy character; and if we were able before, to detect special vitiation in the red corpuscles, we may expect to find special improvement in these. And this is precisely the result which follows the treatment I am recommending."

Without entering into technical detail, I think what has been said represents the present state of our knowledge concerning paludal malaria. The plans which have been advised for its adjuvant treatment, I can recommend to you after an ample experience, and if they should be sanctioned by your reason and used in your practice, I cannot doubt that the benefits will at least be equal to what I have mentioned as the result of my own experience.

MEDICAL PROGRESS.

EFFECT OF LANOLIN ON MICRO-ORGANISMS.—The results of GOTTSTEIN'S experiments on this subject are thus given in the *Deutsche Med. Zeitung*, Berlin: 1. The bacteria which effect a spontaneous decomposition of glycerine fats belong presumably to the class of anaërobes; a number of aërobe germs (even the putrefactive) perish on a medium containing fat. But the term of continuance of this retrogressive metamorphosis is decided by the proportion of fat to the other ingredients of the nutritive medium. 2. Free fat contains anaërobes for some days after it is exposed; but lanolin has under similar circumstances neither aërobe nor anaërobe germs. 3. Glycerine fats may be so impregnated with bacteria that the latter can pass through the fat to the lower-lying infectible substances, while lanolin cannot be permeated by bacteria. It acts, therefore, as a preventive of decomposition when laid over infectible substances.—*British Medical Journal*, Nov. 10, 1888.

A DIAGNOSTIC SIGN OF NEPHRITIS.—GEISLER says that the elimination of iodide of potassium by the kidneys may be used as a diagnostic sign of nephritis. While the quantity of albumin increases with the accentuation of the lesions of the glomeruli of the kidneys, the rapidity of elimination of iodide of potassium remains normal. But it is diminished as the lesion of the canaliculi of the kidneys becomes more advanced. This is true in both the chronic and acute forms of nephritis.—*Pract.*, No. 27, 1888.

TARTRATE OF THALLIN INJECTIONS are recommended for gonorrhœa, in 1:50 and 1:100 naphthol solutions. Use three injections of one-half or one-third a syringeful daily.

SATURDAY, DECEMBER 1, 1888.

THE NUMBER AND VARIETY OF MEDICAL SOCIETIES.

In *THE JOURNAL* for November 24, 1888, we made some suggestions in answer to the question, whether the formation and support of so many American associations of medical specialists was not tending to the disintegration and final destruction of the American Medical Association as the great representative organization of the profession in this country? While we then freely expressed our conviction that no fears need be entertained of such a result in the future, and candidly admitted that such National specialist organizations were affording a useful field for some members of the profession to work in, who would not work in any other, another and perhaps more important question demands more attention than it has yet received. Are there any evils arising, or likely to arise, from the organization of an unlimited number and variety of medical societies, each acting independently of all the others?

If, as is the fact, we have in each of the larger cities from six to ten independent medical societies, and in each State not only one general State medical society but several State societies of specialists, and then several societies receiving members from parts of several States, does it not almost necessarily tend to so far divide the time and work of the working members of the profession as to impair the efficiency and influence of the whole? No member of the profession engaged in active practice, can well afford to attend and

sustain properly more than one local medical society meeting weekly or semi-monthly; one State society meeting annually or semi-annually; and one National society meeting annually in different parts of the country.

If he divides his time with a larger number of societies, he lessens the amount that he can give any one; or if he tries to contribute something to a larger number he either presents the results of his work so hastily and imperfectly prepared as to be of little value, or he reads substantially the same paper to three or four different medical societies as an original contribution to each. One of the most important defects in the contributions to medical societies in this country is, incompleteness, arising from insufficient time and attention given to their preparations. But those who advocate the organization of as many independent medical societies, local, State, and National, as there are special departments of the science and art of medicine, evidently overlook one of the fundamental and important objects to be gained by professional society organizations. This object is, to bring those representing all classes and interests in the profession *together* at stated intervals, that by personal acquaintance, friendly intercourse, and mutual interchange of knowledge, personal and sectional prejudices should be removed, the common-stock of professional knowledge and skill increased and more widely diffused, and the unity and power of the profession as a whole greatly strengthened. Instead of fostering this fundamental object, the organization of an independent society, local, State and National, for every *specialty* in medicine, only tends to keep the cultivators of each isolated from the others; or if any attempt is made to obviate this by bringing representatives of all these together once in three or five years, it still leaves the great body of educated and faithful general practitioners out of recognition, and directly makes the line of distinction between the specialist and practitioner more plain, and more rapidly develops into full maturity the class distinctions of specialists, consultants and general practitioners with their inevitable jealousies and bickerings.

On the other hand, with one general medical society in each city, county and State, with one National society constituted of representatives from all these, and in each of which the practitioners of every department of the healing art

can meet on a common platform; and yet within the regulations of each, Sections sufficient to accommodate the more detailed work of every legitimate specialty; we would have the most complete professional organization possible; combining all the inspiration, homogeneity and power derived from unity, with every advantage for detailed scientific work in the several Sections, that could be afforded by any number of separate specialist organizations. We wish every intelligent, earnest worker in our profession would give more thought to this subject. If in "union and harmony there is strength," it logically follows that in segregation and discord there is weakness.

RHEUMATISMAL METATARSAL OSTEO-PERIOSTITIS.

The apparently unrecognized, or but little recognized disease of infantrymen, is written of in an interesting article in the *Revue Générale de Clinique et de Théraputique*, of October 25, by CH. ELOY. It may be considered as an œdema localized at the head of the two or three metatarsal bones of the centre of the foot, with an accompanying osteo-periostitis. The cases on record number 20, 8 having been reported by Pauzat in 1887, 11 by Poulet 1888, and one by Eloy. Of the 19 cases of Pauzat and Poulet, 2 were old soldiers. In all of the cases the symptoms came on after marching. In all the cases there were two cardinal symptoms: painful œdema and periostitis. The œdema was first manifested, after one or more long marches, by a swelling limited to the level of the dorsal face of the two or three intermediate metatarsals, and sometimes invaded the root of the toes or effaced the tendinous projection of the extensors. It is of medium hardness, depressible under the finger, and accompanied by slight elevation of the temperature. The pain accompanying it is not spontaneous, but is provoked by pressure and by movements. There is a very manifest arthralgia of the metatarso-phalangeal joints when a toe is seized with a pair of forceps and repeatedly flexed. The localized œdema and the pain are the signs of the beginning of the affection, and characterize the first period. After some time periostosis begins. The finger, and sometimes the eye, of the observer can detect swelling of the metatarsals. This periostosis may appear as early as the fourth day, but usually

not until the twelfth or fifteenth day. Whether it comes on early or late, the periostosis persists for several weeks, or even months after the disappearance of the œdema, the diminution of the pain, and the return of the tendinous prominences to their normal form. These phenomena characterize the second period—the osteoplastic phase.

There are two views as to the pathogenesis of this affection. On the one hand it is claimed that it is a traumatic periostitis; on the other, it is thought to be an osteo-periostitis of rheumatismal origin, and consequently the local manifestation of a specific affection. Pauzat excludes all constitutional influence. His patients were young men, 21 or 22 years old, robust, vigorous, with well-formed feet, but unfitted by previous occupation for long marches. Fatigue, then, seems to be a predisposing cause. Seven of the eight cases reported by Pauzat were those of soldiers recently enlisted. But it is a curious fact that the affection was never bilateral; one foot only was affected, and one as often as the other. Is it not possible, however, that men that have not learned the whole art of walking perfectly, use one foot more than the other—put more strain on one foot. Some football players, for example, can kick with only one foot, while others use each foot with equal facility. Can the shoes be responsible for the affection? In view of the small number of soldiers affected this does not seem probable; but it would be interesting to have some statistics from the Spanish army, in which, we believe, the soldiers use sandals on the march.

The prognosis of the affection is serious, according to Pauzat; good, according to Poulet. Pauzat's unfavorable opinion is based on the fact that the osteo-periostitis places the patient out of actual service for a considerable time. Poulet bases his prognosis on the fact that the malady does not prevent the patient from entering the service again.

The treatment of the affection, according to Eloy, consists in rest, elevation and immobilization of the foot, and topical applications and compression. Topical revulsives, such as the iodides, should be used in the osteoplastic stage of the disease.

"CHEESINE," the most recent American product, is said to be a product of skim milk, alkali, and hog fats.

OUTBREAKS OF MALIGNANT DIPHTHERIA.

Since November 1st outbreaks of malignant diphtheria have been reported from Brainerd, Minn., Moline, Ill., New Orleans, Wabash, Ind., Galesburg, Ill., Coxsackie, N. Y., Waterloo, Iowa, Oxford Junction, Iowa, and several other places. During the month of October, at Moline, Ill., there were 69 cases and 12 deaths, and during the first 17 days of November 41 cases, with a smaller death-rate. In New Orleans diphtheria has been more than usually prevalent during the past few months. The extent to which it has prevailed in New Orleans of late months is something of a novelty for that city. The statistics of the Board of Health show that the number of cases of diphtheria has been on the increase for several years past, and this year the virulence of the disease has redoubled. This fact, taken in conjunction with the almost total immunity from this trouble enjoyed in the past by this city, proves the existence in New Orleans of conditions and unsanitary influences that did not previously prevail.

In New Orleans the disease is not particularly virulent in localities, but is scattered all over the city with the exception of the Carrollton district, where no cases have occurred. It has attacked indiscriminately white and black, and has visited as well the homes of the rich as the abodes of poverty. The system of isolating the sick by flagging the dwellings in which diphtheria exists has proved effective, as the number of cases is steadily diminishing, so that there is every prospect that the disease will soon be stamped out. During the first 16 days in August there were 69 cases, during a like period in September 77 cases, in October 58 cases, and during the same number of days in the present month but 44 cases were reported. Whilst fighting the disease, the Board of Health has watched every detail that might throw light on the causes producing it. All infected premises have been thoroughly examined as to local and surrounding sanitary conditions, and all information has been carefully tabulated. The Board of Health officials complain of the utter indifference shown by citizens generally to sanitary measures. This accusation, whilst probably just, is one that can be brought against the citizens of many other communities than New Orleans.

In Wabash, Ind., more than a dozen deaths had occurred up to Nov. 18. Dispatches from Wabash

state that "the malady was at first thought by local physicians to be membranous croup, and was so treated, but at a council held it was decided that it is diphtheria. The scourge is confined to children whose ages range from 1 to 10 years. Every case has so far resisted treatment and proven fatal, the patient dying within two or three days. The symptoms are all similar to those seen in croup of the most malignant form."

At Oxford Junction the epidemic is now subdued, but while it lasted there were 190 cases and 42 deaths. At Waterloo, Iowa, the town officials issued a "quarantine" proclamation, closing indefinitely all schools, churches and Sunday schools, and ordering that all persons dying of the disease be buried within twenty-four hours.

At Coxsackie, N. Y., diphtheria was spread in the following manner: The body of a child, aged 9 years, who died of diphtheria at Gunderland, was brought to that village in an open wagon Nov. 10, not disinfected, and buried there. The coffin was opened at the grave and viewed by the members of the family. Since then of those who viewed the body, an aunt died on the 12th, a brother aged 4, on the 14th. The State Board notified the Health Officer that he must quarantine any persons affected with the disease.

A dispatch of November 19 says: "Diphtheria is still raging in Galesburg, Ill. Many deaths are reported and many new cases are daily coming to light. The health officers are making a thorough investigation as to its causes, and have just come to the conclusion that the water in the school building had something to do with it, and consequently have ordered it shut off."

Diphtheria made its appearance in Vermillion County, Ill., about Nov. 14, and soon broke out in the village of Rossville. Cases exist in many families. The public schools were all closed on Nov. 23. No religious services will be held in any church for several Sundays, and no public meetings of any kind will be allowed in the village for four weeks. Business is retarded, and the citizens are greatly alarmed over the malignancy of the disease, but hope by strict measures to prevent its further spread.

Diphtheria is properly classed among the preventable diseases. In spite of this, and of the many and repeated outbreaks of the disease, two of the most difficult things known to sanitarians are to get the people interested in sanitary meas-

ures to an extent sufficient to assist health officers, and to get the newspapers to print really valuable sanitary information. It seems to be a singular trait of the human mind that makes people so blind to their own best interests. Civilized man can be touched most easily through his pocketbook, and sanitary workers should lose no opportunity of showing the people what a good investment, from a financial point of view, health service is.

EDITORIAL NOTES.

DISEASE-RIDDEN INDIANS.—Indian Agent Jones, of the Berthold Agency, has made application to the Department for a physician who shall remain constantly at the Agency. This request is the result of hurried examination of the health of the Indians. Mr. Jones was recently appointed. He finds that disease runs rampant among the entire Indian community. The Indians at this Agency are in a most deplorable condition. In the past their health has been neglected, they have been permitted to roam about the country and, as a result, some members of the tribe have returned to their camps laden with disease, which has spread to nearly every Indian at the Agency. It is understood that the request for a physician has been granted, and that steps will be taken to prevent the further spread of disease among the tribes. The condition of affairs at the Agency in the past has not only ruined the health of the Indians, but has been a constant menace to the whites with whom the Indians necessarily associated. So great became this danger that the county and city authorities were alarmed, and the Mayor of Bismarck was compelled to serve notice on the former Agent that if he did not keep his Indians on the reservation an investigation of the matter would be demanded. Agent Jones hopes to be able to check the disease and promises to keep the Indians on the reservation.

CHOLERA AND CROWDED ROOMS.—DR. DELOS RIOS gives as the result of his prolonged investigations of the subject the following remarkable statistics bearing upon the mortality of cholera, in relation to the number of persons occupying one room when attacked by it: Of 10,000 persons attacked by cholera, and living one person in a room, 68 died; of 10,000 attacked, where there

were one or two persons to a room, 131 died; of 10,000 persons who were attacked, living two to four to the room, 219 died; finally, of 10,000 persons attacked, living four or more to the room, 327 died. No data appear as to the varying size of the rooms, which must, of course, have constituted an important factor in their hygienic character—as must also have been their location in the upper or lower stories, etc.

THE INFANT HOSPITAL AT VIRGINIA BEACH.—This institution, the benefits of which cannot be doubted, appeals to the hearts of all parents, and the noble efforts of those who have had the matter in charge should be encouraged by such liberal contributions as will enable them to continue it and greatly extend the field of usefulness of the sanitarium. The last report shows that the hospital has done good work during the past summer. Mothers are allowed to accompany their children to the hospital, and thus the managers are relieved of much responsibility, and the mothers are materially benefited, not only in health, but in learning the necessity of careful diet and cleanliness for their children. The Virginia Beach Railway furnishes free transportation to mothers and children to and from the hospital.

A VICTIM TO THE MORPHINE HABIT.—The son of a late prominent Chicago lawyer was recently picked up unconscious in the street from the effects of morphine. He said at the station house the next day that his life had been wrecked by following his physician's advice. Six years ago he was recommended to take morphine as an antidote for his appetite for drink. The habit grew upon him until he became wholly a slave to it. He has spent one year in the Washingtonian Home without being cured of the appetite. It is possible that the unfortunate man told the truth, but it is probable that he did not. One can scarcely imagine a physician so ignorant of therapeutics or so devoid of moral sense as to substitute the morphine for the alcohol habit—unless he were a charlatan of the most disgraceful type.

DIRTY MATTRESS FILLING.—At the meeting of the Provincial Board of Health of Ontario on Nov. 9 a letter from a doctor in Guelph was read, enclosing a sample of the wool batting found in a mattress direct from the manufacturer's hands. It was a collection of the dirty odds and

ends about the floor of a woolen factory, including the sweepings. It had an offensive smell and was stated to have a most pernicious effect on the health of the unfortunate people who have to sleep on such beds. The letter concluded by urging upon the Board of Health the necessity of pressing on the Government to have an inspector appointed wherever such manufactures exist, with power to prevent such "abominable outrages upon the health of the unsuspecting public."

EPIDEMIC OF FIBRINOUS PNEUMONIA.—At the recent Congress of Polish Physicians and Naturalists at Lemberg, JAWORSKI and CHROSTOWSKI mentioned a small epidemic of fibrinous pneumonia observed by them. There were five cases of the disease in one house; the patients had been employed in cleaning out a ditch. It was found that the house in which these cases occurred had not been free from pneumonia since 1860. The pneumococcus of Friedländer was found in the exudation taken from the lungs of these patients by means of the needle of a Pravaz' syringe, and also in the earth of the ditch mentioned.

TO INVESTIGATE CATTLE DISEASE.—The Bureau of Animal Industry has requested Dr. Bowhill, of San Francisco to proceed forthwith to San Diego, in connection with the investigation into the cattle diseases on the Pacific coast. Dr. Bowhill will take all apparatus necessary to explain to Boards of Supervisors, and others who may be interested, the means by which different diseases may be discovered and controlled. His mission is purely a protective one, and so far as he is aware there is no increase in the mortality of cattle, nor any new disease developing.

HEALTH AT GREAT ELEVATIONS.—Dr. A. Tucker Wise, in a recently published work, advises patients afflicted with the following diseases to refrain from seeking health at high elevations: Diseases of the brain, heart, or large vessels; tendency to articular rheumatism; kidney diseases (during winter); acute inflammations of throat or larynx; some diseases of bladder or prostate; also, persons somewhat advanced in years should not visit the mountains unless the circulating system is sound.

AN OPENING FOR HOSPITAL INTERNES.—It is said that a circular will soon be issued from the Surgeon-General's office to the resident physicians

of all the civil hospitals in the country for the purpose of giving them an opportunity to appear before a board of medical officers in May, 1889, and enter the army on that date if they so desire, it being the special wish of the Surgeon-General to secure for the medical corps of the army the services of young men who have gained practical experience in their profession by a residence in the large city hospitals.

THE AMERICAN PUBLIC HEALTH ASSOCIATION closed its annual meeting at Milwaukee November 23. The following were chosen officers for the ensuing year: President, Dr. H. A. Johnson, of Chicago; Vice-Presidents, Dr. Jerome Cochran, of Mobile, and Dr. Frederick Montizambert, of Quebec; Secretary, Dr. I. A. Watson, of Concord; Treasurer, Dr. J. Berrien Lindsley, of Nashville. Brooklyn, N. Y., was selected as the place for the next annual meeting.

A NATIONAL BOARD OF HEALTH.—The Richmond, Va., Chamber of Commerce has received a memorial from the Chamber of Commerce, of New Orleans, asking the assistance of the Chamber in the matter of getting legislation to create a National board of health. Hon. George L. Christian, a member of the board, will examine into the matter and give his views.

"DR." CLARKE'S CLERK FINED.—Conrad Lunds, a clerk in "Dr." Clarke's office on Clark street, Chicago, has been fined \$100 and costs for practicing medicine without a license. The prosecution was brought by the State Board of Health, and is an outcome of the failure hitherto of its efforts to suppress "Dr." Clarke's business as a "specialist."

ACUTE GASTRITIS, not yellow fever was the malady of a young woman removed to Bellevue Hospital on Nov. 17, with "symptoms of yellow fever." She died next morning. Even had she had yellow fever, her removal was wholly unnecessary, and probably contributed to her death.

THE PENNSYLVANIA STATE MEDICAL SOCIETY will meet in Pittsburgh in June, 1889. Drs. E. A. Wood and Wm. S. Foster have been selected by the local profession as Chairman and Secretary of the Reception Committee.

DR. J. ADAMS ALLEN, of Chicago, has recently given his library of more than 2,000 volumes to the Presbyterian Hospital of this city.

SOCIETY PROCEEDINGS.

Medical Society of Virginia.

Nineteenth Annual Session, held at Norfolk, Virginia, Oct. 23, 24, and 25, 1888.

(Concluded from page 749.)

FRIDAY, OCTOBER 26—THIRD DAY.

THE PRESIDENT IN THE CHAIR.

DR. JOHN B. HAMILTON, Surgeon-General U. S. Marine Hospital Service, was introduced as an invited guest and, in response to requests, gave an

ACCOUNT OF THE EPIDEMIC OF YELLOW FEVER
IN FLORIDA.

He said he could not hope to say anything in the nature of *instruction* to this old and distinguished Association, especially as what he shall say is entirely unpremeditated and without preparation. But in epidemiology *history* is always interesting, and he will therefore briefly give the outline history of the epidemic of yellow fever now existing in the State of Florida.

Last year the yellow fever appeared in Key West in the family of a restaurant keeper by the name of Baker. It appears that a family of Bolios, who had kept hotel in Havana in various places, the last being called the *Quinta-Avenida* (Fifth Avenue Hotel), unfortunately for Florida, emigrated to Key West. Their household effects, under the regulations governing the regular lines of steamers, could not be shipped by them, so they shipped their effects, consisting of bedding and various articles of furniture, by an irregular "tramp," not now running, called the "Cochran." There was no objection officially made at Key West, as there was neither Government nor local quarantine, and these were landed and stored above Baker's restaurant. The Baker family died of the fever, and thus the fever started and rapidly became epidemic. The Government, under the operation of that section of the statutes forbidding interference with local authorities, did nothing except, on request of the Governor, to aid the local board, established a dispensary and paid the expenses of the city hospital. To enable the speedy depopulation of the city, a refuge camp was established at Egmont Key, at the mouth of Tampa Bay. No case from Egmont communicated the disease.

The first cases in Tampa were kept secret from August to October 21. A family of Italians by the name of Turk, fruit dealers, brought the fever into Tampa. The steamers had refused, under orders from the Hillsborough County Board of Health, to bring fruit from Havana or Key West. These Italians finding it impossible to continue in business set up a smuggling line and brought

fruit by way of Punta Gorda Bay, and overland to Tampa. For this purpose the man Turk and his assistant Peep, or "Pete," made frequent surreptitious visits to Key West while the disease was there epidemic, and blankets were purchased in the infected city, and used while on the overland trip and brought to Tampa. It is a significant fact that the whole family of the Italians were the first taken sick, that they were not publicly known to have been out of the town, although the fact is now known. The measures taken by the Government were simply to conform to the wishes of the Governor to aid the Hillsborough County Board of Health. The duty of preventing the spread of the disease was undertaken by the Florida State Protective Association, an organization consisting of one representative from each County Board of Health, under the presidency of Dr. King Wyley, of Sanford. In December the Association raised the quarantine against Tampa; the County Board of Health asserted that the disease had disappeared, but unfortunately the disease had not been stamped out, and although the cases of fever lingered all winter in Tampa its existence there was bitterly denied.

From Tampa the disease spread to Plant City, Manatee and other places, and it is now believed that the fever was at Jacksonville as early as February. Dr. Guit  ras, of the Marine Hospital Service, an acknowledged expert, says that, in his judgment, at least two of the cases of "society fever," of which there were over thirty reported in Jacksonville in that month, had the well-marked clinical history of yellow fever. Nine of these cases died. Dr. Potts treated cases in Bay Street in June, and there were probably cases continuously until the formal announcement was made.

So-called isolated cases had been reported in Jacksonville after the case in Bay street had been treated in June by Dr. Potts, but that the local authorities denied the presence of an epidemic and placed a guard around each case. This state of things existed until August 26, when the spread of the disease in Jacksonville became so great, cases springing up at various points in the city, that could not be traced to any of the so-called isolated cases, that the authorities had to declare the disease epidemic.

The disease had been introduced in Decatur, Alabama, by a man who had gone from Jacksonville while all of the cases in that city had been reported under guard. His ticket had been from some point outside of the infected city, and consequently he was not denied admittance.

The fever had been introduced in Gainesville and Fernandina by baseball players who had played a game of ball in Jacksonville before the epidemic nature of the disease had been declared and then returned to these cities.

He then went on to explain the Government work at Camp Perry, and said that since its

establishment there had been only one death from yellow fever in the fever hospital at the Camp. He said that the experience of the physicians at the camp went to show that five days was the incubative period, and that when persons had been in the Camp for that length of time and did not develop the disease, there was no danger of their having it, no person having spent ten days in the camp had developed the fever after leaving the station.

He spoke of the lack of local inspection at Tampa where the disease first appeared this season, and said that if the first cases had been reported that there would probably have been no epidemic, and he also said that he had proof to show that when the case of McCormack was reported as the first in Jacksonville, that the fever was even then epidemic.

He also stated that while the fever was raging at Key West, he, at the request of several health officers, had prepared a bill providing for the establishment of a State Board of Health, but it was laid on the table by the Florida Legislature through motives of false economy.

He concluded by saying that the inspection of Florida cities, ordered by the Government, had developed the fact that the yellow fever was epidemic in both Enterprise and Fernandina.

DR. RANDOLPH BARKSDALE, of Petersburg, read a

REPORT ON PSYCHOLOGY AND NEUROLOGY.

He sketched the history of the treatment of insanity. Over 2,000 years ago, insanity was believed to be a state of possession by the devil, and the treatment was directed towards driving the devil out, and punishment of the person for letting the devil get control of him. Hippocrates was the first to cast off such superstition, and announced that insanity was the result of disease of the brain; that the mind—the soul—could not be diseased, and his doctrines prevailed and resulted in improved treatment. But after the fall of the Roman Empire these doctrines passed away, and again the insane became the victims of persecution and of punishment. And it was not until 1795 that Pinel inaugurated the reformation in treatment which prevails to this day. He announced that insanity is a disease, and that the insane are therefore entitled to all the care and tenderness of the skilled physician and nurse. From year to year since then, improvements in the provisions for and care of the insane have taken place, as of other diseases. Under the head of *neurology*, Dr. Barksdale referred to some of the approved uses of electricity in medicine, and also noted approvingly some statements of Dr. Seguin and others regarding the localization of cerebral functions with reference to the help of such information to the surgeon in selecting the site for trephining in certain obscure brain injuries or diseases.

DR. W. D. HOOPER, of Liberty, in his REPORT ON THE ADVANCES IN THE PRACTICE OF MEDICINE,

gave a brief account of the progress of the germ theory in the last twelve months, saying the advance had been in rather a "retrograde" direction, as Sternberg proves Freire's inoculations for yellow fever are a failure, and M. Gibier has not discovered the true germ of that disease, but thinks he himself has! Pasteur's patients are dying of hydrophobia, but Koch is more fortunate with his bacillus, as it was accepted as true by a recent Congress for the study of tuberculosis which met in Paris. Pasteur thinks M. Gamalier, of Odessa, has discovered a true inoculation for cholera, and referred his communication to the prize committee of the Academy of Sciences.

DR. BARKSDALE also gave a description of a NEW METHOD OF TREATING ULCERATED BLADDER WITH PROSTATIC ENLARGEMENT, BY RE- PEATED IRRIGATIONS

of that organ with warm salt and water holding iodoform in suspension. He uses for the purpose a Y-shaped tube 5 inches long, attaching the tube of a fountain syringe to one of the short arms and a rubber tube to the other, while the long arm of the tube is inserted into the catheter. He reported two cases: the first, aged 78 years, relieved on his deathbed when all other means had failed; the second, aged 75, perfectly cured, as he now sleeps all night without emptying his bladder, and rides horseback during the day.

DR. C. E. BUSEY, of Lynchburg, read a paper on

CULTIVATION OF VOCAL MUSIC IN THE SCHOOLS, AS ONE OF THE MEANS OF PREVENTING PHTHISIS.

He states it as a well-known fact that those nations which are given to the culture of vocal music are strong, vigorous races, with broad, expansive chests. If an hour a day was devoted in our public schools to the development of vocal music, there would not be the sad spectacle of the drooping, withered, hollow-chested, round-shouldered children. There is too great a tendency to sacrifice physical health upon the altar of learning. Vocal music is gymnastic exercise of the lungs, producing increased expansion of the lungs by development of the lung tissue itself. The lungs in improved breeds of cattle, which naturally take little exercise and are domiciled much of the time, are considerably reduced in size when compared with those animals running at liberty; and so it is with the human race who lead inactive lives caused by civilization. Phthisis generally begins at the apices of the lungs because these parts are more inactive, and because the bronchial tubes are so arranged that they carry the inspired air with greater facility to the bases than to the api-

ces. During inactivity, a person will ordinarily breathe about 480 cubic inches of air per minute. If he will walk at the rate of six miles an hour, he will breathe 3,260 cubic inches. In singing, this increases more than in walking, as to sing well requires all of the capacity of the lungs. The instructor of vocal music, in addition to his musical education, should understand the anatomy and physiology of the respiratory organs.

DR. G. McDONALD, of Union, West Virginia, in his

REPORT ON OBSTETRICS,

spoke of the value of *asepsis and antisepsis in midwifery*, repeating the precautions that have time and again been repeated in books, journals, etc. As to *anæsthetics* in labor, chloral hydrate, in 15 grain doses, every half hour or so, is better during the early stages of labor than chloroform, which latter should be reserved for the final throes. The placenta is best expelled by *Credé's method*. It has been recommended to pack the cavity of the uterus with iodoform gauze in cases of *post-partum hæmorrhage*, after the failure of ergot, hot or cold injections, etc.; but as a rule, empty the uterus promptly and cause tonic contraction of the organ. In cases of *placenta prævia* the tampon may undoubtedly be used to gain time for sufficient dilatation of the os uteri in order to use the hand, etc. When a case of *occipito-posterior position* is seen before rupture of the membranes, and before the head and shoulders become impacted in the pelvis, introduce the aseptic hand (patient under chloroform), catch the head between the fingers and thumb and rotate the occiput forwards, when the labor may proceed as a normal case. In regard to *face presentations*, when the chin falls into the hollow of the sacrum, bring the chin forward, and hold it there until expelled. The Veit-Smellie method is advocated for delivery of the after-coming head in *breech cases*. The importance of laparotomy, etc., in rare instances in obstetrics is dwelt upon.

Dr. W. W. Parker, of Richmond, read a paper entitled: *What is the Duty of a Doctor to a Patient suffering from Malignant Disease?*

DR. GEO. B. McCORKLE, of Covington, presented the

REPORT ON DISEASES OF WOMEN.

In regard to *electricity*, he presented the conclusions of Dr. Martin, of Chicago, as to its use in the treatment of fibroids of the uterus: It is free from danger; is absolutely painless; invariably checks excessive hæmorrhage; rapidly reduces the size of the tumors; stops neuralgic pains; its use is based upon the principle of the exact dosage of electricity. Electricity has likewise proved useful in removing tumors from the female breast, in the practice of Dr. Garnett, of Berlin. It has also been useful in increasing the flow of milk in mothers' breasts. Dr. Byford uses electricity in

paralysis of the bladder after inflammation has subsided. Dr. Rockwell has successfully used it in amenorrhœa. Even in a case of complete extrusion of the uterus electricity has been successfully resorted to to retain the organ in place after its reposition. Operative procedures seem to be taking the place of pessaries. Dilating and curetting the uterine cavity for numerous growths on its inner surface, etc., are again becoming very popular.

Dr. Oscar Wiley, of Salem, made the report on *Diseases of Children*.

Dr. M. A. Rust read a paper entitled: *Mysticism in the Development of Medicine*.

Dr. William L. Robinson, of Danville, read a paper on the *Conduct of Enciente Women before and after Delivery*.

DR. ALFRED C. PALMER, of Norfolk, read the

REPORT ON OPHTHALMOLOGY.

He divided his subject so as to speak systematically of whatever concerned: (1) the lids, lachrymal apparatus and orbit; (2) the cornea, conjunctiva and sclera; (3) accommodation, refraction and the motor apparatus; (4) the uveal tract, vitreous, aqueous, and lenses; (5) the retina and optic nerve.

DR. JOHN T. FRANCIS, of Norfolk, presented the

REPORT ON OTOTOLOGY AND LARYNGOLOGY.

He first speaks of the pathology of aural vertigo, and then, with reference to the treatment of otorrhœa, says that lactic acid attacks only the fungous growths, and diminishes the secretion and causes the odor to disappear. Pilocarpin is also recommended. Photoxylin (20 per cent. solution) closed a perforation in the membrana tympani. The ear is first syringed with boracic acid solution, and dried with absorbent cotton. Then the edges of the perforation are painted several times until the perforation is covered. He reports a case of serious injury to the ear as a result of simply syringing that organ for a purulent discharge. The remainder of the report is on laryngology, and speaks mostly of laryngeal tumors, tracheotomy, chronic and atrophic rhinitis, hay fever, etc.

DR. CHAS. M. SHIELDS, of Richmond, read a paper on

ENLARGED TONSILS—WHAT SHALL WE DO WITH THEM?

He had never seen a single case of true hypertrophied tonsils permanently removed by the application of any of the astringents, absorbents or mild caustics suggested, or by the injection into their substance of iodine, ergotin, etc. In soft varieties or in the case of young children where prompt contraction of the bloodvessels follows cutting, he uses the tonsillotome; but in the hard fibrous varieties and in adults, where there is

danger of alarming hemorrhage he prefers the use of the galvano-cautery.

From six to eight points over the surface of the tonsil should be touched with the moxa point electrode heated to a red heat at one sitting, and usually from four to eight sittings are required to shrink up the tonsil thoroughly. If a 10 per cent. solution of cocaine is first applied, patients will usually complain of no pain. Dr. Shield's conclusions were: In all cases except in young children or where the tonsil is very soft, the galvano-cautery method of removal is to be preferred, because, 1st. The tonsil can be more nearly restored to its normal proportions. 2nd. Irregularly shaped masses of hypertrophied tissue can be removed that could not be encircled by the tonsillotome. 3rd. The effect seems to be more permanent. 4th. It is devoid of all danger.

Dr. Joseph A. White, of Richmond Va., read a paper on *Improved means of Diagnosis and Surgical Treatment of Nasal and Throat Troubles, with practical remarks.*

After the adoption of a number of resolutions simply of State or local interest, etc., this session of the society adjourned *sine die*.

The social features were excursions, drivings, banquetings, etc. Of course they were popular, as they were all well prepared, and most hospitably given. The effect of this session upon the profession of this State was most excellent.

Obstetrical Society of Philadelphia.

Stated Meeting, October 4, 1888.

THE PRESIDENT, T. M. DRYSDALE, M.D.,
IN THE CHAIR.

(Continued from page 753.)

DR. W. J. TAYLOR presented with the following remarks:

THREE UTERINE MYOMATA.

These three tumors were removed to-day from a case of considerable interest. The patient, a woman, æt. 30 years, was married on the 7th of last May. On the 20th she had her last menstruation, and from that time considered herself pregnant. The abdomen began to swell and she had a good deal of pain. A few days ago she sent for me, and I found her with the abdomen much enlarged and presenting the symptoms of pregnancy. On the right side, however, there was a hard mass which puzzled me very much. She was seen by Drs. W. W. Keen and B. C. Hirst, and the conclusion was reached that an operation was necessary. To-day abdominal section was made. It was found that the uterus contained a fetus, and that there were three fibroid tumors: the largest was sub-peritoneal, the smallest was

attached by a small pedicle, and the second in size was also sub-peritoneal. These were removed, and the patient is at present doing well.

DR. W. W. KEEN said that Dr. Taylor had not done himself justice in his modest narration of the steps of the operation and in his reference to the question of diagnosis. When I saw the patient last Monday it was a question whether the large mass on the right side was a uterine myomata or a tubal pregnancy. It had grown rapidly and *pari passu* with the uterus. Two facts in favor of its being a solid tumor were its density, and the fact that the pulsation of the aorta could be distinctly heard with the stethoscope at every point over the tumor. Its rapid growth seemed to be opposed to the idea of myoma. Dr. Hirst was of the opinion that it was a tubal pregnancy, at the same time recognizing an intra-uterine fetus also. She had albuminuria. When Dr. Taylor opened the abdomen two large tumors presented, which coalesced below but were separated above. Passing the hand into the abdomen the left tube and ovary were found normal. On the right side, it was at first not possible to recognize the ovary and tube, but by enlarging the incision the hand was passed well down, and the ovary and tube found. By the side of this tube was a vein considerably larger than my thumb. The pregnant uterus was recognized as the large tumor to the left. It was soft, elastic, and dark in color. That to the right was recognized as a neoplasm. While I lifted with difficulty the upper end of the tumor, Dr. Taylor incised its capsule and enucleated it until he came to the attachment to the uterus which was over a space of three or four inches in diameter, when the weight of the tumor then caused the uterine tissue to tear, and the large sinuses began to bleed freely. I next grasped the pedicle with the thumbs and forefingers of both hands while he stripped off the sac. The tumor was thus quickly removed, and the uterine tissue and the wall of the sac were seized with large hæmostatics and hæmorrhage controlled. It was necessary at several points to introduce sutures into the uterine wall itself to control the bleeding. The redundant portion of the sac of the tumor was cut away, and the edges brought together with the continuous catgut suture; a drainage tube was passed down into its cavity. In at least two places, and possibly four, there were, upon the uterine wall small masses about half the size of my little finger-nail. These looked like beginning malignant tumors. From the appearance and the rapidity of the growth, I think this may be a sarcomatous tumor, though it is possibly a simple myoma.

DR. PARVIN thought that there was one point that even Dr. Keen had omitted. He saw the operation and the great mass of the tumor was included between the layers of the R. broad liga-

ment, so that the first incision was through the anterior layer of the ligament. Formerly in removing a subperitoneal fibroid from the posterior surface of the uterus the pedicle partially tore while the ligature was being applied and there was free hæmorrhage. He finally succeeded in stopping the bleeding by the use of the continuous catgut suture, after other measures had failed.

DR. HIRST said that Dr. Keen had certainly expressed his views. The symptoms pointed strongly to extra-uterine pregnancy. If the case had been allowed to go on to term Cæsarean section would have been required, as the tumor filled up the pelvis. He had looked up this subject of injuries to the pregnant uterus and had found some interesting cases. In one case the woman was thrown to the ground and jumped upon when six months pregnant. The fœtus was killed but she went on to term. In another case trachelorrhaphy was performed during the second month of pregnancy. This case went on to term. In another instance a number of leeches were applied to the cervix of a pregnant uterus without any interruption to pregnancy. In a case I had last spring the woman was squeezed between a bale of goods and the wall and was seriously injured, but she went on to term. A German operator has such confidence in his ability to plunge a trocar into the uterus without doing harm that he advocates the occasional withdrawal by aspiration of the liquid in hydramnios with very great distension of the uterus, allowing the child to go on to term.

DR. PARISH said that the removal of ovarian tumors during pregnancy was recognized as a proper operation, but that the removal of uterine subperitoneal fibroid tumors during pregnancy was not a proper operation, except under certain special circumstances. The injuries necessarily inflicted on the uterus in their removal are liable to induce abortion. It would be interesting to have the further history of this case. The microscope alone could determine the character of this growth. Under ordinary circumstances the rapidity of the growth would point to sarcoma, but it is well-known that in pregnancy fibroid tumors occasionally take on a rapid growth. He supposed that Dr. Hirst did not refer to the cases he had cited as indicating rules of practice. It must be the urgency of the condition which justifies operations on the pregnant uterus. While pregnancy may go on after injuries to the uterus there are numerous unreported cases where the opposite has been the result. Where a subperitoneal tumor can be lifted from the pelvis pregnancy may go on.

DR. J. PRICE thought that obstetrically the case was one of great importance. Some time ago he had called attention to three parallel cases. They all went to term with a pelvic tumor and died undelivered. The question of differential diagnosis

scarcely concerned many operators at present, all that was required was the knowledge that there was a tumor present. We should never wait until the patient's general health has been impaired, as this is a departure from that generally followed in general surgery.

DR. HOFFMAN had been recently consulted by a woman who stated that she was pregnant and that at previous labors the baby "had to be mashed up." The pelvic cavity was found to be filled with a tumor and she was advised to undergo an operation for its removal. This she refused. It seemed to him that there could be no doubt of the propriety of immediate operation in cases like the one before him.

DR. B. F. BAER believed that in this case, after the exploratory incision had been made and it was found that no extra-uterine pregnancy existed, it would have been better to have closed the incision than to have removed this amply located solid tumor; but since the removal was determined upon, it would have been better to have amputated the uterus at the neck than to have permitted it to remain with a great wound in its side and in the broad ligament. It is not likely that, after such a serious operation, the pregnancy will go on to term anyway, and abortion occurring within a short time after the operation will certainly add to the risks of the patient. He asked if there were any subjective signs of pregnancy (extra-uterine) in this case, such as the peculiar pains, uterine hæmorrhage or discharge of decidua?

DR. KEEN thought that the removal of the uterus would have been a wholly unjustifiable procedure. It was possible that the woman might miscarry, but it was also possible that she would go to term. It has been shown that pregnancy is not necessarily a bar to operation. Not only would the sacrifice of the fœtus have been unjustifiable, but hysterectomy would have made a young married woman sterile. The added dangers of hysterectomy, too, might have turned the scale against the patient.

DR. M. PRICE asked if Dr. Baer would expect to have uterine hæmorrhage in a case of extra-uterine pregnancy where there was also a fœtus in the uterine cavity?

DR. B. F. BAER said that he would expect in such a condition that, as the result of the extra-uterine irritation, abortion would take place, and then we would have both hæmorrhage and decidua. In regard to the removal of the uterus in this case, it seemed that Dr. Keen condemned the procedure because of his anxiety to save the child. He, however, believed that the child would have had a better chance for its life if nothing had been done. But if operative measures were imperative, then he still held to his former opinion. In answer to still further questioning from Dr. M. Price, he said that he believed that hæmorrhage may occur and the extra-uterine sac remain unrup-

tured. He had seen a case which supported that view. The patient, after missing her menses for two months, was one day seized with severe pain in the right iliac region, which was followed by shock. She fell in her yard, and when her physician arrived he found a condition of shock as well as hæmorrhage. A few weeks later she had a similar attack. He was then sent for and the diagnosis of extra-uterine pregnancy arrived at. This was five years ago, and Thomas' method of operating by the vagina and opening the sac with a hot knife was followed. The sac was found with no evidence of rupture in it. The liquor amnii was clear and no evidence of hæmorrhage into the cyst, which there would have been had a rupture taken place. The fœtus was indeed alive. The patient died on the fifth day after operation.

DR. WM. J. TAYLOR closed the discussion by saying that in this case the tumor was absolutely fixed. The woman's general condition was poor; the pulse 120; the patient not able to eat; had suffered intense pain and diarrhœa for a number of days previously. The tumor was also growing rapidly. The urgency of the case seemed to call for some relief. There was albuminuria. If the matter had been allowed to go on to term—provided the woman had lived that long—the risks to both mother and child would have been greater than they were at the present time.

Transmissibility of Tetanus—Infectious Nature of Tetanus—Osseous Grafts—Corrosive Sublimate in Cholera—Management of Abortion—Periodical Neuralgia of the Cornea.

Professor Verneuil, who introduced into science the notion of the contagiousness of tetanus, and its equine origin, follows the development of this idea with great solicitude and embraces every opportunity of justifying his views on the subject. At a recent meeting of the Academy of Medicine he read a report on two papers, the one by Dr. P. Berger, entitled, "The transmissibility of tetanus from man to man," and the other by Dr. G. Richelot "on the infectious nature of tetanus." M. Verneuil reviewed the whole subject in a most masterly manner, and terminated his report with the following conclusions: 1. The intra-human transmission which although demonstrated as yet by only a small number of facts, cannot be contested in principle. 2. This transmission does not appear to be affected by the atmosphere, but is accomplished by direct or indirect contact. 3. The first mode, that is, "immediate contagion," is not as yet established by any decisive fact. The

second mode, or "mediate contagion," is supported, on the contrary, by a great number of clinical proofs. 4. It is sometimes still very difficult to discover the veritable agent of transfer among the numerous and varied intermediary means graduated between the first tetanic subject and those that follow. 5. This research should be prosecuted with pertinacity, for it alone will teach us to prevent a mode of extension of the malady, which is perhaps rare, but altogether indisputable.

At the same meeting Dr. A. Guérin presented a certain number of osseous grafts practiced by Dr. Mossé, of Montpellier. These operations were on the rabbit, the dog, and the monkey, and were thus classified: 1. Re-implantation of a fragment of the skull removed by trephining. 2. Transplantation of the fragment on an animal of the same species. 3. Transplantation on an animal of a different species. It is sufficient to preserve the periosteum for this re-implantation to be effected with success.

Dr. Yvert, a French army surgeon, has made a communication to the Academy of Sciences on the treatment of cholera with corrosive sublimate. During his service at Tonquin he had occasion to employ the drug in doses of from 2 to 4 centigrams a day, in subjects affected with cholera. The results were most encouraging, for of 45 patients suffering from the disease, 9 only had succumbed, thus reducing the mortality to 20 per cent. He had also recourse to the same medication in a certain number of convalescent soldiers, the greater number of whom had suffered from dysentery, and although they had sojourned in the midst of cholera patients, not one was affected by the cholera epidemic, thanks to the absorption of the bichloride of mercury which was administered to them as a preventive measure.

The following are rules published by Dr. Nitot in the *Revue Obstétricale* on the management of cases of abortion: 1. In presence of the imminence of abortion we should, if there is still time, notwithstanding a commencement of uterine contractions and loss of blood, prevent the abortion being effected, in prescribing absolute rest in bed, enemata of laudanum or, what is still better, hypodermic injections of morphia. 2. If the abortion is inevitable, we should favor the spontaneous expulsion of the product of conception, opposing at the same time a too abundant loss of blood. With this view absolute rest should be insisted on, and vaginal injections, which should be hot (45° C.) and antiseptic, should be prescribed every two or three hours. These will favor the dilatation of the uterine neck and combat the hæmorrhage. However, should the flow of blood be too abundant, vaginal plugging should be employed. This measure will act not only in arresting the hæmorrhage, but will hasten the termination of the abortion. The administration of the ergot of

rye should be guarded against; as the drug, in provoking contractions of the neck of the womb, is liable to imprison the placenta in the uterine cavity. 3. But if, in spite of these precautions, the abortion, clearly established, lingers some time; if the placenta, adherent or not, remains imprisoned in the uterine cavity, it would be better to accomplish artificial delivery than to temporize longer, and to empty the uterus in order to avoid the dangers of a tardy abortion, such as hæmorrhage more or less grave, or septicæmia, which are likely to occur. In acting thus, the future safety of the patient is ensured. 4. Finally, if it should become necessary to combat one of these dreaded complications which may break out, such as septic fever or repeated abundant hæmorrhage, which the plugging and the hot injections might have arrested only momentarily, no more hesitation should be permitted. It will be necessary to intervene with the fingers if the uterus is in a state of sufficient dilatation, or in practicing the antiseptic "cavage" or cleansing of the uterus after previous dilatation, if this is necessary; for to wait longer, in this case, would be to expose the life of the patient.

Dr. Granché, of Lyons, has described an affection which is rather frequent, consisting in a sort of periodical and ill-defined neuralgia of the cornea, following a very slight traumatism of this membrane. The traumatism consists, more frequently, in a simple grazing by the leaf of a shrub, the finger of a little child, or any other soft body which cannot do much hurt. To this condition he has applied the term "traumatic keratalgia." Soon after the accident, although the cornea presents no excoriation, the patient suffers a good deal and periodically from neuralgic phenomena which are reproduced irregularly for some years, like rheumatoid pains. One can only attribute these accidents to a slight neuritis of one or more of the ciliary nervous filaments of the cornea which are found in the sphere of action of this slight traumatism. If the stronger traumatisms of the cornea, such as those resulting from the incrustation of a splinter of iron, or any other metal, do not leave behind them similar neuralgias, it is because the nervous filaments touched had been destroyed, and not simply bruised. The only remedy which appears to relieve these patients is the employment of cocaine. A. B.

THE PASTEUR INSTITUTE in Paris was formally opened on November 14 by President Carnot. Pasteur himself was present and was loudly cheered by the people.

TRINITY MEDICAL DINNER.—The Students of Trinity Medical College held their twelfth annual banquet on Nov. 13. More than 250 guests were present.

DOMESTIC CORRESPONDENCE.

LETTER FROM BOSTON.

(FROM OUR OWN CORRESPONDENT.)

Acute Lobar Pneumonia in Children—Pelvic Hæmatocle; Operation by Laparotomy; Suture of Cyst to Abdominal Wall and Drainage—Laparotomy for Volvulus—Removal of a large part of the Frontal Bone for Compound Fracture.

At the meeting of the Suffolk District Medical Society, on Oct. 27, Dr. C. W. Townsend read an extensive and interesting paper on "Acute Lobar Pneumonia in Children." He said that we should make a distinction between *lobar* and *lobular or broncho-pneumonia*, although this is not generally done, it being customary to find both forms classed together in the returns as pneumonia. Lobar pneumonia is an acute specific disease, whereas lobular or broncho-pneumonia is a secondary affection and is almost always secondary to a bronchitis affecting the smaller bronchi. When a pneumonia is spoken of in young children, the lobular pneumonia is the form that is generally understood to be in consideration. This, however, should not be the case; for the lobar form is by no means uncommon, the writer having recently seen 42 cases of undoubted lobar pneumonia in children under 10 years of age. Of these cases, 5 occurred in children under 1 year of age; 5 occurred in children between 1 and 2 years old, and 7 occurred in children between 2 and 3 years old.

Probably the reason that pneumonitis is so frequently overlooked in infants is because the signs that are diagnostic of pneumonitis in adults are in large measure either modified or wanting. These signs are:

1. Sudden onset with rigor.
 2. Localized pain in the affected side.
 3. Cough.
 4. Rusty expectoration.
 5. A characteristic high temperature.
1. The onset is generally sudden in young children, and the chills or rigors are almost always absent. In their stead are found vomiting and convulsions.
2. Pain is frequently absent in young children, and when present it may be elsewhere than in the affected side, *e.g.*, it is frequently referred to the abdomen.
3. The cough is generally present. It is frequently loose and hacking. In 6 of the above-mentioned 42 cases there was no cough at the onset. It frequently increases as the disease increases.
4. The rusty expectoration is generally absent in young children, for it is swallowed. Of the above cases only 3 cases, *æt.* respectively 7, 8, and 10 years, had any rusty expectoration.
5. The increasing high temperature is charac-

teristic in young children as found in 37 of the above cases, 29 cases ending by crisis and 8 by lysis. The seventh day was generally found favorable for the crisis, the temperature rose continuously up to 104° as a rule. The highest temperature reached was 106° in one case. None failed to reach 103° .

A change in the disposition of the child generally occurs after the crisis. The cough frequently continues. The physical signs generally coincide with the temperature. They may be tardy in making their appearance. The true crepitant râle is frequently not found but vocal fremitus and consolidation will decide. It is highly probable that some of the so-called acute febriculas of children are really pneumonia. The expiratory moan and dilatation of the alar nasi are not characteristic. Cerebral pneumonia frequently means only pneumonia in a child of a highly nervous organization, and there are no cerebral or meningeal lesions. Herpes occurred in only three of the above cases.

The diagnosis must be frequently made from the history. Pneumonia is sudden and broncho-pneumonia is less sudden and generally follows bronchitis. In pneumonia the temperature is higher than in broncho-pneumonia. Broncho-pneumonia never ends in crisis. The prognosis is generally favorable. Of the above-mentioned 42 cases only two died and both of these were feeble, ill-nourished children. One was rachitic and the other had a large abscess. Several cases have been reported where children have been born with pneumonia, the disease having commenced in utero. All of these cases are fatal.

In the discussion, Dr. Francis Minot said, that the fact is important of the great frequency with which it can be *demonstrated* that pneumonia has a local organ, *i.e.*, that it is infectious. It may occur successively in the same house in different seasons.

Dr. T. M. Rotch said that in children with pneumonia there is an absence of the physical signs that occur in adults. The child may be totally unconscious for a week, and then the pneumonia shows itself. He was reminded of two cases in one family, one child being aged $3\frac{1}{2}$ years and the other 16 months. In the elder the attack commenced twelve or fourteen hours later than in the younger. For five days both were unconscious and vomiting, with symptoms of acute milk poisoning, and there were no physical signs. Their food was changed and they remained unconscious for three days more, when the left lungs showed a commencing solid area and the temperature went up, together with the other signs of a real pneumonia. This continued for seven days and ended in crisis, and all along the signs in the elder child continued to be twelve or fourteen hours later than in the younger. In the treatment antifebrin is a good thing, but in

administering it we should avoid giving it at the time of the crisis, when it is dangerous.

In the absence of the writer, the Secretary read a paper by Dr. C. B. Porter, on "Pelvic Hæmatocele. Operation by Laparotomy,—Suture of Cyst to Abdominal Wound and Drainage,—Recovery." The patient was 30 years old and unmarried. Her catamenia had been regular and normal every four weeks, the flow lasting four days. During the two weeks previous to being seen, she had been loosing appetite and strength. Her bowels were regular, and she continued to work at her ordinary duties. One night she was awakened from sleep by severe pain in the left iliac region at first and then shifted. Then there was vomiting and small movements. A swelling appeared in the right iliac region. On examination she was lying on her back with her legs extended and her countenance had an anxious expression. Pulse 68. A swelling was found in the right iliac region. Per vaginam the cervix uteri was found movable. The urine was examined and was normal. The vomiting became troublesome. The urine had to be drawn with the catheter. On the third day it was decided to operate. An incision was made one inch above Poupart's ligament. A large cystic tumor with tense walls at once came into view. This was stitched to the edges of the wound, so as to shut off the abdominal cavity and it was then opened. Three pints of a dark bloody fluid were then removed. This was examined by the microscope and was found to contain no formed elements. It was probably ascitic fluid with blood. There were no clots. A large drainage tube was put in and the sac was washed with a hot solution of sulpho-naphthol. The third day the discharge was colored. Three weeks afterwards when it was syringed, some threads of necrosed membrane came away. There was steady recovery, and seven weeks after the operation (near 16th) there was very little discharge. On April 3rd she left the hospital.

Dr. M. L. Richardson read a paper on "Laparotomy for Volvulus." On the 3d of July he operated on a man 57 years old, who had a history as follows: On the 28th of June he had a chill and a sensation of fullness of the abdomen and twisting of the intestines, as he himself expressed it. Two days later even a cup of tea caused him to feel very full. His temperature was 99.4 . There was pain in the left iliac region. July 2d, there was no pain and he had two liquid stools. Note this improvement. On July 3d he had a collapse. When seen he had dulness in abdomen, most marked on left side in iliac region. There was vomiting and now severe signs of obstruction. Laparotomy determined upon as a forlorn hope. On opening the abdomen the intestines presented and were distended and of a dark purple color. A twist was found in the small intestine. The

coil was very heavy and filled with fluid. Death followed in a very few hours. At the autopsy the next day the intestines were removed *en masse* and were sent to Dr. Fitz for examination. The blood in the mesenteric system was found clotted and at this stage he was undecided whether this was due to a thrombus in the portal system or to volvulus.

In conclusion, Dr. Richardson said that in grave cases of doubt, with symptoms of obstruction, an early operation is advisable. By an exploratory incision much is gained and little is lost.

In discussion Dr. E. N. Whittier said that he had seen the case in consultation. Note how deceptive the case was. At first the man seemed so little sick that he objected to being kept at home in bed. Note also the two semi-liquid discharges which were deceptive. The mass felt was easily moulded and doughy. The twist was in the upper part of the small intestine, and so the tumor was very low down for it.

Dr. H. E. Marion, in whose practice the case occurred, said that it had not been mentioned that there was vomiting of stercoraceous matter, and also that the necrosis affected nearly the whole length of the small intestines.

Dr. F. B. Harrington reported a case of "Removal of a large part of the Frontal Bone for Compound Fracture. Recovery." The patient was a brakeman, æt. 28, who had been struck on the forehead by a bridge. The face was very much swollen and crepitus could be distinctly found over the middle of the forehead. The patient was dull and heavy, but would answer questions. On incision the frontal bone was found in several pieces overlapping one another irregularly, and in all about one-third of the bone was removed, the exact portion being marked out on a skull that was passed around. The dura mater was found to be wounded in one or two places. The wound was packed with iodoform gauze. For a few days he had delirium, but he recovered rapidly and became rational. When discharged there was a slight pulsation over the cicatrix.

N.

Use of the Heel in Walking.

Dear Sir:—Will you permit me to enter my protest against the editorial entitled, "How to Dress and Walk," which appeared in THE JOURNAL of the 17th inst.? I will not be so uncharitable as to suppose that there was any intentional misrepresentation of the fair exponent of the Delsartian method of walking. But she certainly performed her task poorly, if the women of the Physical Culture Club failed as completely to understand that method as the editor of THE JOURNAL seems to have failed.

I am familiar with the Delsartian teaching on that subject, and I will say that it does not at all

teach one to ignore the use and support of the heel in walking. It does teach, however, and I believe, correctly, that the weight of the body should *not* be thrown upon the heel. I must decidedly disagree with the editorial writer when he asserts that "the heel was made to step on, to bear the *whole weight* of the body at the beginning of the step." The weight of the body at the beginning of the step, is mainly borne on the ball of the *other foot*. The heel of the advancing foot should barely touch the ground before the ball is also brought down, and it is not till after this that the weight of the body should be transferred to that foot, and then the spring for the next step naturally brings the principal weight upon the *ball* of the foot.

Let anyone try to walk across the floor, putting his whole weight upon the heel of the advancing foot, and even if he does not fall over, I think the experiment will convince him that this method of walking is no more physiological than it is Delsartian. The lady to whom reference was made, is a good Delsartian teacher, and she does not, by precept nor by example, *usually* teach her pupils to let their heels fall into "innocuous desuetude." Respectfully yours,

A SISTER.

November 21, 1888.

[The lecture in question was reported in a Chicago paper. The lecturer's remarks on "how to walk" were quoted directly in the paper. The only meaning that could be given the words quoted was, that a person should not step on the heel in walking. It was not intended to say in the editorial article that the walker should rest for a time upon the heel of the advancing foot.]

BOOK REVIEWS.

AN ILLUSTRATED ENCYCLOPÆDIC MEDICAL DICTIONARY.—Being a Dictionary of the Technical Terms used by Writers on Medicine and the Collateral Sciences, in the Latin, English, French and German Languages. By Frank P. Foster, M.D., Editor of the *New York Medical Journal*, with the Collaboration of William C. Ayres, M.D., New Orleans; Edward B. Bronson, M.D., New York; Charles Stedman Bull, M.D., New York; Henry C. Coe, M.D., New York; Andrew F. Currier, M.D., New York; Alexander Duane, M.D., New York; Simon H. Gage, Ithica, N.Y.; Henry J. Garrigues, M.D., New York; Charles B. Kelsey, M.D., New York; Russell H. Nevins, M.D., New York; Burt G. Wilder, M.D., Ithica, N. Y. Vol. I. With Illustrations; 4to, pp. xii, 752. A—Ca. New York: D. Appleton & Co. 1888.

We have, at last, a medical dictionary that will

repay consultation, and never leave the consulter in doubt. For years the tempers of medical men have been sorely tried by the incompleteness of existing dictionaries, by no means complete when they were published, and necessarily more incomplete as each succeeding year added new words or gave new meanings to terms already in use.

There is but one medical dictionary in any way comparable to the one under consideration, and that is the "New Sydenham Society's Lexicon of Medicine and the Allied Sciences," which has two great faults. It includes a great deal that has no bearing upon medicine or the allied sciences, and its orthography, particularly in regard to German and other foreign words, is singularly defective. Obvious errors in other dictionaries are repeated, showing that much has been taken for granted. Every page of Foster's Dictionary shows accurate work in every respect. It contains no unnecessary matter. Voluminous as the work may appear, it is really compact, concise in definition; the definitions are in almost all cases logical definitions, without the patience-trying defining by synonyms.

This is not an English medical dictionary only; it is also a Latin, or a French, or German medical dictionary. For example, in reading a French work we may turn to this dictionary to find the meaning of a French medical word. We can but regret that it is not also an Italian medical dictionary. Under "Auf" we find more than four pages of German words; under "Aus" more than five pages of German words. Under *Acide* we find fourteen pages, averaging almost 200 titles to a page. *Bacillus* takes up nine pages, *bacterium* three pages, *bone* about eight pages. The analyses of the mineral waters are given when mineral springs are named.

As must be apparent, an exhaustive review of a dictionary in a short space is an impossibility; one meets with the same difficulty encountered by the Hibernian, who found that the subject changed too often for him to become deeply interested. The writer is familiar with almost every lexicon that a medical man can use. Foster's Dictionary is far beyond and above all; the whole work shows completeness and faithfulness, and this can be said of no other medical dictionary. No physician's library will be complete until all the volumes of Foster's Dictionary are on its shelves.

MISCELLANEOUS.

ASSOCIATION OF ACTING ASSISTANT SURGEONS, U. S. ARMY.—Those familiar with the army medical history of the frontier for the past twenty or thirty years will readily bear witness to the faithful and intelligent discharge of their duties, by the Acting Assistant Surgeons of the U. S. A. In fort and in camp, on the long overland expedi-

tion, or in the Indian wars, these men have done their duty as faithfully and with the same professional efficacy as if they had been regularly commissioned officers. Indeed, if they have not borne the burden and heat of the day, certainly their honorable records deserve recognition and preservation. An association of past and present Acting Assistant Surgeons of the United States Army has been formed for the purpose of securing, so far as possible, a correct history of those who have served in this capacity, and also for mutual protection and benefit. The Association desires to obtain a complete list of all medical men who have served as Acting Assistant Surgeons, in the United States Army, and, so far as possible, their complete medical history, date and place of birth, date and place of graduation, date of appointment, medical service and stations, list of contributions to medical literature, inventions, etc., date of termination of service, professional positions held in civil life, present residence and address. All information from friends concerning deceased A. A. Surgeons will be gratefully received. All past and present Acting Assistant Surgeons are cordially invited to become members of the Association. The badge of the Association is the Geneva red cross. The enrollment fee is \$1.00. The necessary blanks will be forwarded upon application to

W. THORNTON PARKER, M.D., Recorder A. A. A. S.,
Newport, R. I.

THE TELEPHONE has been extensively used by physicians in prescribing for their patients, and the story of the doctor who ordered its parents to hold the baby to the 'phone until it coughed and then ordered some medicine for whooping cough is familiar. But a St. Paul doctor will probably not trust this useful invention hereafter. He was requested over the wire to visit a sick child two miles away the other night, and not wanting to go prescribed over the 'phone and went back to bed. On making the call the next day he found the patient doing very well under the care of another doctor, and went back with a change of mind regarding the usefulness of Professor Bell's invention.—*Chicago Herald*.

THE TRI-STATE MEDICAL ASSOCIATION met at Memphis on Nov. 13. The attendance was large, embracing many of the leading physicians of Mississippi, Arkansas and Tennessee. The Association elected the following officers:

President—Dr. S. W. Sanford, Tennessee.
First Vice-President—Dr. J. Y. Murray, Mississippi.
Second Vice-President—Dr. L. L. Battle, Arkansas.
Third Vice-President—Dr. J. A. Battle, Tennessee.
Secretary—Dr. S. A. Rogers, Memphis.
Assistant Secretary—Dr. R. W. Pate, Memphis.
Treasurer—Dr. T. J. Crofford, Tennessee.

THE THIRD ANNUAL STATE SANITARY CONVENTION, under the auspices of the Kansas State Board of Health, will be held in the city of Emporia, Kansas, on Wednesday and Thursday, December 5 and 6, 1888. The first session will commence on Wednesday at 7:30 P.M. An interesting series of papers and discussions are promised. All the sessions are open and free for the public to attend. President, Hon. John R. Wright; Secretaries, J. W. Redden, M.D., of Topeka, and A. M. Hawont, of Emporia.

HEALTH OF CALIFORNIA.—Dr. G. G. Tyrrell, Secretary of the State Board of Health, in his report for October, says: Reports received from seventy-nine localities return the mortality for the month of October as 902 decedents in an estimated population of 726,850, or an annual death-rate of 14.88.

DR. F. H. PAYNE, who has practiced medicine for the last twelve years in Berkeley, Cal., has been appointed Director of Physical Culture at the University of California.

ADULTERATION OF FOOD.—According to a report made by the Dominion analyst, out of 909 food samples analyzed, 25 per cent. were found to be adulterated. Out of 81 samples of baking powder 45 were adulterated with foreign matter; 33 out of 117 samples of coffee were impure. Cream of tartar, bicarbonate of soda, butter, milk, mustard, and spices were largely composed of foreign and deleterious substances. A member of the Dominion parliament, Mr. Cochran, representing East Northumberland, has recently been heavily fined for selling skim milk. The minister of inland revenue states that he is determined to check the production and sale of spurious and adulterated articles of food, and with that object in view is prosecuting the offending parties when their guilt has been discovered.

THE ALBANY HOSPITAL.—From the report made for the year ended October 1, by Treasurer Joseph W. Russell, it is shown that 954 patients, 680 of whom were beneficiaries, were treated in the hospital and 7,421 in the dispensary, and 4,233 gratuitous prescriptions were given out. The expenses were \$28,200. Of this sum \$10,620 was spent for provisions and supplies and over \$3,000 for medicines and medical supplies. The endowment fund was increased during the year by \$11,000, sending it up to \$39,000. The legacies amount to \$11,000, and the year's donations and subscriptions to \$7,000. Because of the extraordinary demand on the institution donations are solicited.

THE NATIONAL COMMISSIONER OF EDUCATION has issued a report upon examinations of pupils for imperfections of eye-sight. Color blindness is more prevalent amongst boys than girls. Of optical affections the highest percentage is found amongst children of Irish, Swedish and German blood. The lowest is amongst those of American, French, Scotch and English extraction.

SMALL-POX PANIC IN SCRANTON.—The breaking out of small-pox at Kingston, Luzerne Co., Pa., has caused a panic through that section, which is in the very heart of the Wyoming coal regions. Close by are the mining towns of Luzerne, Maltby, Laskville, Edwardsville and Plymouth. Kingston lies between these places and Wilkesbarre, the county seat.

TYPHOID FEVER IN AN ORPHAN SCHOOL.—Reports from the Soldiers' Orphan School at McAllisterville, Juniata Co., Pa., confirm the rumor of the ravages of typhoid fever among the pupils of that school. It is known that a number of cases exist, and the number is estimated at from twenty-five to forty.

THE MEDICO-CHIRURGICAL SOCIETY OF THE DISTRICT OF COLUMBIA has elected the following officers for the ensuing year: Robert Reyburn, President; A. Tangusta, first Vice-President; P. P. Werner, second Vice-President; F. J. Shadd, Treasurer; J. R. Francis, Librarian; L. A. Harver, Secretary; and S. R. Watts, Corresponding Secretary.

DR. H. D. SCHMIDT, the distinguished pathologist, for many years connected with the Charity Hospital of New Orleans, died on Nov. 23.

THE NORTH TEXAS MEDICAL ASSOCIATION will meet in Sherman, Texas, Tuesday, Wednesday and Thursday, December 11th, 12th and 13th, 1888.

LOS ANGELES SEWERAGE, it is said, is now receiving the much needed attention of Dr. H. S. Orme, a member of the California State Board of Health.

"THE TONGUE" is the title of a new paper, edited by a New Jersey physician. Of course all the doctors will wish to see it.

DR. PERCIVAL H. FLYNN, of New York, died on Nov. 17 in consequence of an overdose of morphia.

A HOSPITAL FOR CONTAGIOUS DISEASES is to be built at Worcester, Mass.

ST. CLAIR COUNTY, Mich., urged to action by the recent small-pox scare at Sarnia, will build a new pest house.

Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department U. S. Army, from November 17, 1888, to November 23, 1888.

Lieut.-Col. Richard H. Alexander, Surgeon, is granted leave of absence for four months, by direction of the Secretary of War, to take effect from the date of his relief from duty as Medical Director Dept. Ariz. by Lieut.-Col. Joseph R. Smith, Surgeon. Par. 11, S. O. 268, A. G. O., Washington, November 16, 1888.

Lieut.-Col. Smith, after being relieved by Lieut.-Col. Alden, will report in person to the commanding officer Dept. of Ariz. for duty as Medical Director of that Department, relieving Lieut.-Col. Richard H. Alexander. Par. 10, S. O. 268, A. G. O., Washington, November 16, 1888.

Surgeon William E. Waters, Vancouver Bks., is granted leave of absence for one month, to take effect on or about the 1st prox., with permission to apply for an extension of one month. Par. 1, S. O. 129, Hdqrs. Dept. of the Columbia, November 9, 1888.

Lieut.-Col. Charles H. Alden, Surgeon, is relieved from further duty at the U. S. Military Academy, West Point, N. Y., and will report in person to the commanding General Dept. of Dakota for duty as Medical Director of that Department, relieving Lieut.-Col. Joseph R. Smith, Surgeon. Par. 10, S. O. 268, A. G. O., Washington, November 16, 1888.

By direction of the Secretary of War, Major Charles Smart, Surgeon, will proceed to Milwaukee, Wis., to represent the Medical Department of the Army at the meeting of the American Public Health Association in that city November 20 to 23, 1888, and upon the adjournment of the Association will return to his proper station. Par. 2, S. O. 268, A. G. O., Washington, November 16, 1888. Capt. Richard C. Newton, Asst. Surgeon, is granted leave of absence for four months, by direction of the Secretary of War. Par. 16, S. O. 272, A. G. O., Washington, November 21, 1888.

By direction of the Secretary of War, the leave of absence granted Capt. Marshall W. Wood, Asst. Surgeon, in S. O. 257, November 3, 1888, from this office, is extended ten days. Par. 12, S. O. 270, A. G. O., Washington, November 19, 1888.

Official List of Changes in the Medical Corps of the U. S. Navy for the Week Ending November 24, 1888.

P. A. Surgeon A. C. Heffinger, ordered to the U. S. Str. "Kearsarge."

Asst. Surgeon Patrick H. Bryant, ordered to the Naval Hospital, Brooklyn, N. Y.

Surgeon Daniel McMurtrie, ordered to the U. S. receiving ship "Vermont."

Surgeon M. C. Dreuman, detached from "Vermont" and to the "Atlantic."

Surgeon G. F. Winslow, detached from the "Atlantic" and placed on waiting orders.

P. A. Surgeon W. A. McClurg, detached from the "Tallapoosa" and to the "Kearsarge."

Asst. Surgeon L. L. von Wedikind, ordered to the "New Hampshire."

P. A. Surgeon A. C. Heffinger, detached from the "Kearsarge" and to the "Tallapoosa."

Surgeon B. F. Stephenson, detached from Navy Yard, Boston, and to the "Wabash."

Medical Director A. S. Oberly, ordered to the U. S. Str. "Richmond."

Surgeon W. H. Jones, detached from the U. S. Str. "Richmond" and wait orders.

REPORT OF FORTY-EIGHT CASES OF ALEXANDER'S OPERATION.

Read before the Section on Gynecology, at the Thirty-ninth Annual Meeting of the American Medical Association, May, 1888.

BY J. H. KELLOGG, M.D.,
OF BATTLE CREEK, MICH.

Since October 29, 1886, I have made the operation of shortening the round ligaments forty-seven (sixty-nine times, Nov. 28, 1888) times. The purpose of this paper is to give a brief summary of the immediate, and so far as determined, the remote results of the operation, some observations respecting the nature and purpose of the round ligaments, a description of a new and simpler mode of operation which overcomes the difficulty of finding the ligaments in certain cases, indications for the operation, and suggestions respecting the after-treatment of cases in which this operation has been performed.

Of this series of cases, the first twelve were reported in a paper presented at the last meeting of this Association. Another report of the first twenty cases of the series was made in a paper read before the Gynecological Section of the International Medical Congress.

The following is a classified statement of the whole series of cases, as regards local conditions for the relief of which the operation was performed:

Retroversion or retroflexion, with prolapse of one or both ovaries, 39 cases.

Complete procidentia, 4 cases.

Prolapse of ovaries, 3 cases.

Anteversion, 1 case.

RESULTS IN 39 CASES OF RETROVERSION AND RETROFLEXION.

Of these cases, nearly one-half of which were operated upon more than one year ago, four have been operated upon within three months, and although they promise exceedingly well, they cannot yet be considered as permanent successes. Of twenty-six of the remaining cases, I will say nothing more than that with one exception the patients are well, that the uterus and ovaries are in normal position, and that the symptoms for

which the operation was performed have disappeared, and show no evidence of returning. In one case the operation is an anatomical success, but the patient still suffers from various local pains, which I believe to be of a neuralgic character. Each of the remaining cases, which were not wholly successful, I will notice in detail, as the unsuccessful cases are those of the greatest interest in the history of any new operation.

Miss B. Condition: sharp, rigid retroflexion, uterus double normal size, cervix just within the ostium vaginae, ovaries enlarged and prolapsed. Operation restored uterus and ovaries to proper position, but the intra-uterine stem occasioned great pain and frequently recurring epileptic seizures, so that it was removed on the third day. Two months after the operation, the uterus was retroflexed, but not so much so as before. The ovaries were out of reach, and the uterus was held well forward. The patient went home without a pessary. Was free from epilepsy for several months. Worked hard in caring for an entire family of sick persons, relapsed, and is now little better than before the operation. I think a posterior colporrhaphy should have been performed, and that the patient should have worn a pessary. This case was the second one operated upon and I had at that time more confidence in the sustaining power of the ligaments than I now have.

Mrs. V. Condition: retroflexion, prolapse of ovaries, and distressing reflex symptoms. The sixth case operated upon. Found ligament upon right side, but failed to draw it out. Closed wound and did not operate upon the other side. Patient is neither better nor worse than before the operation.

Miss L. Retroflexion and ovarian prolapse, the result of subinvolution. Uterus and ovaries restored to good position, but when the patient got upon her feet a small hernia appeared upon the right side. Closed this by a subsequent operation. Patient went home too soon. After a few weeks reported little relief from the operation. Has not been heard from for several months. The ligaments in this case were very small.

Mrs. M. Retroversion and prolapse of ovaries. Ligaments extremely slender. One parted in the attempt to draw it out. A week after the operation, found uterus retroverted. A week later, the

uterus was in normal position. Patient went home soon after the operation. Uterus remained anteverted without artificial support for three months, the patient being well enough to engage in ordinary household duties, and greatly better than before the operation. Allowed the bowels to become very constipated. Strained violently at stool during three or four weeks. Came back for examination. Found uterus partially retroverted. Adjusted a lever pessary, applied electricity daily for three weeks and patient was greatly improved. Uterus remained in position for several hours without artificial support, while before operation the organ became retroverted after replacement as soon as the patient stood upon her feet, unless supported artificially. Patient went home wearing a lever pessary without discomfort, which she could not do before the operation. Considering the disadvantages surrounding this case, I think the operation did fairly well. This was one of the first cases operated upon.

Miss B. Retroversion and prolapse of ovaries. One ovary considerably enlarged. Organs restored to good position by the operation. Patient became homesick and went home soon after the operation. Organs in good position when last seen. Patient not relieved of pain at menstrual period, though pain was less severe than before the operation. Present condition I have been unable to learn.

Miss R. Retroflexion, prolapse, and enlargement of ovaries. Had repeated attacks of cellulitis. Constant ovarian pain. In bed most of time, very weak, anæmic, and suffered extremely at menstrual periods. Ligaments were very slender, and a month after the operation uterus was found slightly retroverted. Ovaries in good position. A lever pessary was placed and worn without discomfort. Since operation patient has had no pain in ovaries, no pain at menstruation, has gained 44 pounds in weight, and is able to walk four miles without inconvenience. She pronounces herself in perfect health, and gives the credit to Alexander's operation. So the case can hardly be regarded as a failure, notwithstanding the inability of the ligaments to hold the uterus in perfect position. I attribute the improved condition of the patient to the restoration of the ovaries to their proper place, which could not have been accomplished in any other way I am acquainted with.

In three other cases I have had a similar experience as regards the failure of the ligaments to hold the uterus perfectly in position. These were all cases of retroflexion, in which the intra-uterine stem gave pain or created so much reflex disturbance as to necessitate its removal. The ovaries were well held up, however, in each of these cases, and serious reflex disturbances, as nausea and vomiting at the menstrual period, or after, disappeared after the operation and have not returned.

A pessary can now be worn without inconvenience, although before it could not be tolerated for twenty-four hours. These cases may fairly be regarded as at least partial successes. In summing up the results of thirty-nine cases of retrodisplacement and ovarian prolapse, I may say that twenty-six were wholly successful, seven were improved, and only two were total failures, four being yet undetermined. I hope to have the opportunity to operate again in one of the cases of complete failure, and believe success may be secured.

RESULTS IN 4 CASES OF PROCIDENTIA.

Mrs. R. Complete procidentia of seven years' standing. I had temporarily relieved the patient three years before by a posterior colporrhaphy, but after a second child-birth, the difficulty returned. Operated October 29, 1886. Found ligaments very slender, but the uterus and ovaries were held well in place. Patient went home in six weeks, against my protest, and in spite of my earnest advice, would not wear a pessary. Remained well, notwithstanding, with uterus in good position, for six months, or so long as she took good care of herself. Then the patient engaged in business which required her to be much upon her feet and the old condition soon gave evidence of returning. The patient now reports herself about as bad as before the operation. The patient should have had the posterior colporrhaphy repeated, should have worn a pessary, and should have remained under medical care for a few months after the operation.

Mrs. N. A case of complete procidentia, enormous rectocele and cystocele. Uterus could not be retained by any sort of pessary except an inflated ball, or a pessary with an external support. Found ligaments large, but could not draw them out more than 2½ inches. Organs seemed to be well held up after operation, and all went well for several weeks, when, in straining at stool, the patient forced out the vaginal walls. The fundus was not tilted backward, but the cervix seemed to slide down under the arch of the pubes. The rectocele and cystocele which formerly existed, were but partially reproduced. I desired to perform a colporrhaphy, but the patient thought she would do well enough without it, since the uterus was held well in place by a small inflated ring pessary. The patient's condition is still about the same. Some slight improvement. Patient does not consider the operation a success though her condition is evidently anatomically better than before.

I believe that both the above cases would have been entirely successful if the proper supplementary operations had been performed. I now refuse to operate in cases of this sort unless the patient will agree that all the operations necessary may be performed.

Two other cases of the same sort operated upon more recently, in which the shortening of the ligament has been supplemented by a thorough colporrhaphy, have yielded most excellent results.

RESULTS IN 3 CASES OF OVARIAN PROLAPSE.

In the first case, Miss M., the uterus and ovaries lay in the hollow of the sacrum. The uterus was sharply anteflexed, various sorts of pessaries had been tried and either could not be worn or did no good. In operating, found the ligaments very slender indeed. One was broken. By the shortening of one ligament the fundus was drawn forward, where it has remained. The patient is relieved to a great degree of the pain which she formerly suffered after menstruation, and can wear a small lever pessary, which affords her great relief from backache and other local discomforts.

In two other cases the uterus was anteflexed, otherwise in good position, but both ovaries were prolapsed. In each case one ovary was much enlarged. The ovaries are now in normal position and no enlargement is perceptible. Tenderness and pain in the ovarian region have disappeared. Two of the three cases may be regarded as completely successful, one partially so.

RESULTS IN A CASE OF ANTEVERSION.

Patient, Miss M., aged 33. Complete anteversion. Lower border of fundus was below the arch of the pubes. Patient suffered all the inconvenience usually accompanying this condition. Operation May 31, 1887. Shortening the ligaments, lifted the uterus backward and upward fully 2 inches, where it has remained since the operation. Patient is wholly relieved and enjoys excellent health. Is a laboring woman and works steadily. Has done so for several months. Enjoys good health in every respect. No pessary or artificial support of any kind has been worn since the operation.

Summing up the results of the whole forty-seven cases, I find as follows :

Complete success in 29 cases.

Improvement in 9 cases.

Failure in 3 cases.

Undetermined, but promising excellent results, 6 cases.

I do not think the operation could fairly be considered at fault in either of the three cases of failure. In one case failure was due to want of skill or experience, or the faulty mode of operation, it being one of my first cases, and the old method being employed. Of the other two cases one was due to neglect of proper after-treatment and overdoing on the part of the patient. In the third case failure was due to want of a colporrhaphy. In at least half of the cases in which only improvement was secured, I am confident that with better after-management much better results might be secured. But that the operation

fails in some cases, even when it is an anatomical success, is not a proper ground for condemnation. The same is true of many other surgical procedures. Leaving the undetermined cases out of consideration, I find the failures to be only 7 per cent., while improved cases are 22 per cent., and complete successes, 71 per cent. of the total number operated upon. This is certainly not a bad showing for a new and yet undeveloped operation.

The general skepticism respecting the value of this operation, will, I think, justify me in introducing a few extracts from letters received from patients in response to a circular letter sent out to those upon whom the operation had been performed from six to eighteen months previously. The following is an abstract from a letter from Miss R., whose case I have put down as only a partial success, as the ovaries could still be felt after the operation, though the uterus was placed in good position :

"I feel that I must write and tell you how perfectly well I am. In fact, all my friends look upon my recovery as almost a miracle. Pains and backaches are things unknown to me now. I walk at least a mile every day, and often three or four, and have gained 46 pounds since the operation. I shall be down in a few weeks for an examination to make sure that I am all right. Must say again, I feel simply 'elegant.'"

[Since this paper was written this patient has called upon me, and upon examination I find both uterus and ovaries maintained in good position without a pessary and the patient enjoying absolutely perfect health. No local tenderness anywhere, so that this case was after all a complete success anatomically as well as therapeutically.]

The following letter from Mrs. D. speaks for itself :

"On the 13th day of April, '87, you performed for me the Alexander operation at the Sanitarium, and now enough time has passed to know something of its effects. My good health is a marvel to both myself and my friends. I am so well, so strong, so happy in my good health; and my heart is so full of gratitude to you for the good received at your hands. I am growing stronger all the time, thereby proving your words to be true (that I would not feel all the good effects of my operation for a year). My husband thinks that the money spent is the best investment we ever made. This reads something like the testimonials we read in the patent medicine almanacs, but I don't mean it that way, for I do this of my own free will, because I am so thankful for my good health that I must tell you so."

The following letter is from Mrs. M., who had suffered for many years from retroversion, and flexion and prolapses of the ovaries. Operation was performed about six months previous to the date of her letter, written March 18. She still remains in excellent health :

"In answer to your letter of inquiry of March 12, I reply as follows to your questions in the order in which they are asked:

"1. I am well pleased with the results of the operation.

"2. I think I can safely say I am relieved of all the symptoms I suffered before the operation.

"3. I have had no examination by another physician, and have no means of knowing the present position of the organs. I only judge from the health I enjoy that they occupy their proper position.

"4. I do not suffer from any inconvenience which I did not experience before the operation.

"5. I believe the operation has made me a well woman. I have not enjoyed as good health for several years. I am doing the work for my family of seven except the washing and ironing. I feel that I am able to do that also, but my husband thinks I had better wait a while longer.

"I can hardly express the gratitude I feel daily for the benefit I received from the operation."

A few days after the above was written I examined this patient and found her well, with uterus and ovaries in normal position, and in a healthy condition.

In preparing this paper for the press, I am able to report another case which I have had opportunity to examine since the paper was written, the case of Mrs. N., one of the two cases of procidentia which were reported as failures. I found that the uterus was held forward in good position, and that it had never been down since the operation as formerly, although there had been a protrusion of the vaginal walls. This was much better than I expected, as I supposed by reports from the patient that the uterus had fallen down as before. A small hernia which followed the operation, had nearly closed, and the operation could fairly be called at least a partial success. By the aid of a proper colporrhaphy, I feel confident that the success might have been made complete.

I give below a copy of a letter from Dr. Alexander, received since this paper was written. The letter relates to the case of Miss Y., of Liverpool, England, who consulted me for epilepsy and general ill-health. On examination, found retroversion with prolapse of ovaries. As the epileptic seizures occurred most frequently and severely at the menstrual period, and the patient suffered from the usual pains and inconvenience accompanying retroversion and ovarian prolapse, I performed Alexander's operation, hoping that both the local condition and the nervous disorder might be thereby relieved. After returning to her home, the patient consulted Dr. Alexander, who reported as follows:

Liverpool, Eng., May 21, 1888.

Dear Sir: I have just had the opportunity of examining Miss Y., one of the cases upon

which you have performed the operation that goes by my name. It is with extreme pleasure that I can report the uterus and its appendages as perfectly normal in position and character, and an improvement in all the symptoms, as Miss Y. will describe herself. I congratulate you on the success, and I hope the fits will lessen in time also. But these probably depend on menstruation itself. I am very glad to find from your letter, that you are finding the operation to be a boon when performed in suitable cases.

With kind regards,

Yours very sincerely,

W. ALEXANDER.

OBSERVATIONS RESPECTING THE NATURE AND PURPOSE OF THE ROUND LIGAMENTS.

The fact that the round ligaments are usually found in a relaxed condition, having a slack of from one to two inches, has led to the supposition that they have little to do in sustaining the uterus in its normal position in the pelvis. Indeed, the view has been advanced by some gynecologists that the round ligaments are of no value except as the morphological representatives in woman of the analogous structures in the male. Indeed, in a discussion which occurred in the Gynecological Section of the last International Medical Congress, a professor of gynecology from Canada declared that a large number of dissections which he had made, together with his experience with the operation, had convinced him that these structures were wholly absent in one-half of the women of that country. In reply to the assertion respecting the poverty of Canadian women in round ligaments, it is only necessary to state that Dr. Alexander, of Liverpool, who, at last accounts, had performed this operation nearly ninety times, has never once failed to find the ligaments. In the 47 [69] cases in which I have operated, I have failed in only a single instance, one of my earlier cases, in which I operated by the old method, cutting down upon the external ring. I abandoned the case after operating upon the right side, suspecting that my failure was due to inability to cope with peculiar circumstances—which greater experience might enable me to overcome. I am now fully convinced that my suspicions were correct, and that I had the ligament, but failed to draw it out. I hope to have the opportunity sometime of operating upon this patient again.

In two other of my earlier cases, I had the misfortune to break a slender ligament on one side, although in both cases the remaining ligaments were of sufficiently good size to secure a very considerable degree of improvement in the patient's condition.

Omitting from the enumeration the case upon which I operated upon one side, and adding my forty-six cases to those of Dr. Alexander, we

have a series of more than one hundred and twenty-nine cases, in every one of which both ligaments were present. For my own part, I should as soon expect to find about as many women wanting in ears, eyes, or ovaries, as lacking in round ligaments. I am thoroughly satisfied that these organs are among the most important of the sustaining structures of the uterus. Dr. Alexander sagaciously suggests that while the round ligaments are not continuously in action, they serve a most essential purpose in performing for the uterus the same function served a vessel by its "mooring ropes." While not sustaining the weight of the organ, they prevent its making too extensive excursions downward or backward during such acts as coughing, heavy lifting, jumping, straining, micturition, and defecation.

Strong contractions of the diaphragm and abdominal muscles during coughing, straining, and lifting, crowd the uterus downward into the pelvis with very considerable force. I have endeavored to measure this force by means of a mercurial gauge connected with an air pessary placed in the vagina and filled with water, and found it to be equal to one to four inches of mercury, equivalent to one-half to two pounds per square inch. The descent of the uterus, unless it is strongly anteverted, inclines the fundus backward more and more as the uterus descends along the curve of the pelvis. Without the restraining influence of the round ligaments, there is nothing to prevent the uterus from becoming retroverted from very slight causes, so if these structures were not present, we should find retroversion to be the normal condition of the uterus instead of anteversion. The purpose of the round ligaments is not to sustain the uterus, but, acting through the internal abdominal rings as ropes running over pulleys, they prevent the uterus from being forced so far backward as to allow the intestines, which normally lie behind the fundus of the uterus, to crowd in between the uterus and the bladder, thus producing a permanent backward displacement.

This action of the round ligaments I need not dwell upon, as Dr. Alexander has very clearly and forcibly demonstrated the correctness of this view in his monograph upon this operation, but I wish especially to call attention to what I suppose to be a new observation respecting the action of these ligaments. To perform the function of "mooring ropes," the round ligaments need to be nothing more than fibrous cords. This, indeed, seems to be the general opinion respecting their structure. The following observation proves them to be much more than this, namely, active muscular structures; which is exactly what we should expect to find, considering the matter from a theoretical standpoint, since analogy would give to the round ligaments a structure corresponding

to the cremaster muscle of the spermatic cord.

Having entertained some thoughts of this sort, I made the following experiment upon a case: After cutting down upon the round ligament, and carefully freeing it from the surrounding structures, I drew it out to the full extent, so that the fundus of the uterus was brought close up to the anterior abdominal wall. The ligament was sufficiently detached from the structures of the canal to run freely back and forth without tension upon any of the surrounding structures. I then applied electrical stimulus in each of the following ways:

1. The outer end of the round ligaments, after having been separated from its attachment, was held by an assistant 2 or 3 inches from the surface of the body, and in such a manner that it was not put at all upon the stretch. One pole of the battery was connected with a large flat sponge, placed upon the abdomen 4 or 5 inches above the wound. The circuit was closed by touching the ligament with the other electrode, which consisted of a small copper wire with a bit of absorbent cotton wound about the end and moistened. Immediately on making contact with the ligament, a very distinct contraction occurred, which involved not only the abdominal muscles, but the ligament itself. This was shown by the fact that the ligament was not simply drawn into the wound, but shortened during the contraction.

2. With one electrode placed in the vagina the result was the same, only the contraction was restricted more closely to the ligament and the muscles in the immediate vicinity of the ring.

3. To be doubly sure that the contraction of the ligament was not due to the structure being dragged in by contraction of the abdominal muscles, I carefully isolated the ligament from the body for the length of about 4 inches, and then applied the electrical current by making contact at two points upon the ligament itself about 2 inches apart. There was distinct contraction and shortening of the ligament, with contraction of the abdominal muscles.

4. To make the observation still more positive, I cut off about 2 inches of the ligament, laid it upon a warm, moist towel, and applied wire electrodes to either end. The ligament had been exposed to the air for some time, and had been considerably bruised in drawing it out. Still, slight though very distinct contractions were obtained.

5. I afterwards subjected the portion of the ligament removed to microscopical examination, and found imbedded in its structure large bundles of voluntary muscular fibres. I did not have my stage micrometer at hand at the moment of examination but, comparing the width of the fibres with the diameter of the red blood corpuscles by means of a camera lucida, I determined their width to be about $\frac{1}{10}$ of an inch. For some weeks before examination, the structure had been preserved in a bichromate of potash solution.

In making the tests, I employed three forms of electrical current—using a galvanic current of about 6 milliampères, the faradic current, and a reversing current obtained from a small dynamo. Much the most distinct and vigorous contractions were obtained from the last named current. My first purpose, indeed, in making the observation, was to ascertain the influence of this current upon the round ligaments, as I had found it to be a most efficient agent in stimulating muscular action in other parts of the body. I think it may fairly be inferred from the above observation that the round ligaments are active as well as passive in their function. In other words, they not only act merely as tendinous cords to prevent too great displacement of the uterus, but, when made taut by downward or backward displacement of the uterus, they aid in restoring the organ to its normal position by contracting, and thus lifting it forward. Indeed, their action is probably still more positive in the prevention of downward displacement, since the voluntary muscular fibres of the round ligaments contract simultaneously with the abdominal muscles in such actions as coughing, straining and lifting, so that the slack which is found to exist in post-mortem dissections is doubtless taken up, and the top of the fundus tilted forward at the same moment that the downward pressure is brought to bear, thus diverting the current of downward action toward the hollow of the sacrum and behind the uterus. Is it not on account of this beautiful arrangement of reciprocating muscular action that the hardy women among the peasantry of Continental Europe, as well as the female members of most barbarous tribes of human beings, are enabled to compete in physical endurance with men living under similar conditions? Their well developed round ligaments antagonize the displacing influence of other muscles in such a manner as to protect them from the disorders and malpositions of the uterus to which women of feeble muscular development, and consequently with slender and inefficient round ligaments, are so notoriously subject. In the 47 [69] cases upon which I have operated, I have invariably found the round ligaments large and well developed in women who have from early life been accustomed to such active physical exercises as are calculated to produce a good physique and well developed muscular system; while in women whose habits had been habitually sedentary, or who from early life have had their bodily movements so restricted by tight corsets as to prevent freedom of movement in the muscles of the lower part of the body, I have invariably found the ligaments slender and weak.

A SIMPLE AND IMPROVED METHOD OF OPERATION.

In my first twenty-seven cases, the operation was performed by cutting down upon the external ring as described by Dr. Alexander. In the last

twenty cases, adopting Dr. Alexander's more recent suggestion, I made the incision a little higher up, opening the canal at a point about $\frac{1}{2}$ inch above the border of the external ring, by a division of the intercolumnar fascia. I never find it necessary to make the external incision more than an inch in length. After cutting through the skin, I catch up the underlying structures on either side with snap forceps, and divide the tissues with knife or scissors down to the tendon of the external oblique muscle. Placing the end of the left finger in the wound, I locate exactly the external ring, then draw back the sides of the wound with retractors in such a way as to expose the dark line which marks the location of the intercolumnar fascia. A slight incision is made through the fascia, 3 or 4 lines in length. Taking a strabismus hook in each hand, the opening through the fascia is made to gape by drawing one side back with the hook in the left hand, while the round ligament with its investing fascia is hooked up with the right. In order to secure the round ligament, it is only necessary to adopt the following procedure:

Passing the hook down on the outside of the grayish mass which is seen through the opening in the fascia, press this mass a little toward the center of the body and push the hook down to the lower part of the canal, half or three quarters of an inch below the level of the tendon of the external oblique. Turning the point of the hook inward, a mass of tissue is easily secured and brought out through the opening in the fascia, which will usually be recognized at once by its grayish color and the great number of anastomosing blood vessels as the structure containing the ligament. It is of great importance that the wound should be wholly free from blood, and the dissection a clean one, as by this means only will the natural color and appearance of the structures of the ligament be so preserved as to enable one to identify them. The structures hooked up usually consist of the ligament surrounded by a sheath of fascia, with its accompanying nerve and blood-vessels. To make sure that the ligament shall not escape back into the canal, from which it is not always easy to recover it, I slip a thick carbolized silk thread underneath the whole mass by means of an aneurism needle. The ends are tied together or secured by a pair of snap forceps. The next step in the operation is to carefully enucleate the ligament from the membrane surrounding it, which is easily done by the aid of a strabismus hook. On making a longitudinal slit in the fascia, the smooth, glistening surface of the round ligament is usually readily discovered, and the process of enucleation may be completed in a few minutes. In exceptional cases, the ligament, even at this point, proves to be a mere tendinous thread. On this account, great care should be taken not to sacrifice any chance for securing the

ligament by cutting or breaking off any of the fibres which dip down into the canal toward the internal ring. By repeated trials, even in the most unpromising cases, a fibre will at last be found which, when pulled upon, does not drag upon the borders of the ring to which the fascia surrounding the ligament is attached. Drawing this outward, the operator will be gratified by seeing a smooth, glistening cord emerging from the wound in the direction of the internal ring. Carefully seizing this with the thumb and finger, a little steady traction will bring the ligament fully into view. The ligament may now be dropped into the wound, being still secured by the loop of silk. Place in and over the wound a mass of absorbent cotton, saturated with four thousand solution of mercuric bichloride. After securing the ligament upon the opposite side in the same manner, both the ligaments should be drawn out to the extent of three to five inches. The pouch of peritoneum which forms the canal of Nuck will be seen gradually separating from the ligament as it is steadily pulled forward.

The next procedure is the placing of the silver wires, which should be passed through the tendon of the external oblique, crossing the inguinal canal, and including at least one-half the thickness of the round ligament. Special care should be taken to include in the silver sutures the pouch of peritoneum investing the ligament. I have found two silver sutures to be sufficient. The slit in the inter-columnar fascia is now closed by two or three carbolized silk sutures. At least two of these are also made to include the ligament. Before tying the last suture, the outer portion of the ligament is tucked into the outer end of the inguinal canal. If the ligament has been greatly bruised, however, or if vessels have been tied, so that its nutrition is cut off, the ligament should be brought out through the lower angle of the wound. This is very rarely necessary, if the operator is skilful. The deep and superficial fascia are now carefully brought together by a continuous suture of small chromicized catgut. The skin is united in a similar manner, the silver sutures twisted, and the operation is completed.

In dressing the wounds, I cover them thickly with a mixture of equal parts of iodoform and sub-carbonate of bismuth. Over this is placed a quantity of iodoform charpie, then a thick layer of sterilized cotton, and a snug body bandage, secured by perineal bands, is placed over all. The uterus is supported in position by a lever pessary, which is fitted before the operation. If necessary, this is held up by the hand of an assistant, during the securing of the ligaments by sutures. In cases of retroflexion, the fundus must be held forward by means of a sound, and afterwards kept in place by a stem pessary, unless the flexion is a rigid one, in which case rapid dilatation should be performed before the operation upon the liga-

ments, and a stem pessary placed in position. I have had made a self-retaining stem which I find useful in these cases.

I have operated by this method in 20 [42] cases, and have secured immediate union in every case. Great pains is of course taken to make the operation thoroughly antiseptic. The patient receives a shampoo and is shaved some hours before the operation, and a compress wet with one to four thousand bichloride solution is applied to the parts concerned in the operation. All assistants and nurses, as well as the operator, are required to wear, while in the operating room, large gowns which have been well sterilized by boiling or fumigation. The operator and all who handle instruments, disinfect the hands first by thoroughly scrubbing with hot water and laundry soap, then washing with alcohol or ether, and finally soaking for a minute in a $\frac{1}{2}$ per cent. bichloride solution. The wounds are kept continually moistened by frequent sponging during the operation with one to four thousand bichloride solution.

With the exception of one case, 100.6° F. is the highest temperature shown by any case operated upon in this manner, (now twenty in number,) and the temperature has reached 100° F. in only a few instances.

Another advantage of this simple mode of operation is that it can be performed without ether. The incisions are so small, usually only just large enough to admit the end of the finger, that cocaine answers all requirements for anæsthesia. In my last 18 [40] cases, I have used ether but twice. The patients complain of no pain except for a few seconds at the last, when the ligaments are being drawn out. I usually inject fifteen or twenty minims of an 8 per cent. solution of cocaine under the skin along the line of the first incision, four or five minutes before beginning the operation. No more cocaine is required, as a rule, until the deep fascia is reached. A few minims are dropped over the deep tissues before making the last incision. A few minims more are injected into the inguinal canal before picking up the ligament, and again the needle of the syringe is passed into the canal in the direction of the internal ring, just before drawing the ligaments out. The total amount of cocaine used in a case is usually three to five grains.

Another advantage in the use of cocaine is the fact that the patient is not troubled by subsequent vomiting, as when ether is used. The pain occasioned by the pull upon the ligaments in the straining of a single spell of vomiting after ether, is much greater than the entire amount of pain ordinarily suffered during the operation under cocaine. Patients frequently read a newspaper or a book, or converse jovially with friends during the operation, and declare that they should not be aware from the sensation that any operation was being performed. The great safety of this

operation when performed antiseptically, the little pain involved in it, and the elimination of the small danger involved in the use of ether, by the employment of cocaine, certainly commend to the consideration of gynecologists the question whether so safe and simple a procedure is not greatly to be preferred to dependence upon pessaries, which, at the most, are, with rare exceptions, merely palliative, and are not infrequently attended by great distress and inconvenience on the part of the patient who resorts to their use.

After the operation, the patient is put to bed, a vaginal douche is administered every four to six hours during the day, and one during the night if the patient suffers pain. A narcotic is rarely required. The use of a catheter is seldom necessary, as the patient evacuates the bladder without straining while taking the douche. Before the operation, the patient's bowels are thoroughly evacuated by means of an aloine pill given the night before the operation, and a saline laxative the next morning. The bowels do not move after the operation for two or three days, and then are kept loose by castor oil or some similar laxative. Defecation is aided by warm water enemas, so that no straining is allowed. The silver sutures are removed the seventh or eight day, until which time the dressings are not disturbed. I never use drainage tubes, and see no necessity for their use in this operation. The patient is kept in bed for three or four weeks after the operation, receiving daily massage and general faradization.

At the end of one month, the patient is allowed to get upon her feet, and a course of treatment is begun for the purpose of preventing a relapse into the former condition. Alexander's operation is not to be considered as a radical cure of any form of uterine displacement, but only as a most efficient aid to other means. It restores the uterus to its normal position, and gives it, so to speak, a new chance to stay there if it can. Whether or not it will remain in the position to which it has been restored, depends upon whether other normal conditions, causative and resultant, are or may be removed.

When may Alexander's operation be advantageously employed? In answering this question from the results of my own experience, I should say:

1. That the greatest utility of this operation is in cases of retroflexion and retroversion of long standing, and especially cases in which the uterine displacement is accompanied by prolapse of the ovaries, making the wearing of a pessary painful or intolerable. I think it not improper, however, that a woman who is found to be suffering from retroversion or flexion, without any ovarian complication, should be given an opportunity to choose between an operation which restores the uterus to its normal position, and gives it a fair prospect of remaining in this condition, and many

years, or a lifetime, of dependence upon a pessary, and possibly also upon a specialist to inspect, adjust, and change the supporter to suit varying conditions from year to year.

2. Cases of procidentia, provided the operation is supplemented by other necessary operations, as posterior or anterior colporrhaphy, or both. I am satisfied that much of the prejudice against this operation which exists among physicians is the natural result of too great confidence felt in the operation and the extravagant claims made for it by some of those who were among its early advocates. I think it is now pretty well agreed that Alexander's operation affords only a temporary relief to the subject of complete procidentia unless proper supplementary operations are performed. I have devised a modification of the posterior colporrhaphy of Simon which I find very successful in these as well as other cases requiring a posterior colporrhaphy. The operation consists in the removal of a strip of mucous membrane of proper width upon the posterior wall of the vagina, extending from the labia to a point an inch below the level of the cervix, when the latter is held in its normal position. The inner end of the denuded surface is continued laterally on either side by extending the denudation one-third the circumference of the vagina each way from the median line. Beginning at the apex of each of these cornua, the denuded surface is closed up, first by buried sutures, then by a continuous suture uniting the edges of the mucous membrane. By this means, not only is the vagina narrowed, but a thick strong raphe is made running along the posterior wall, forked at its inner end. The forked end forms a pouch into which the cervix drops, and being prevented from further descent, the action is to tilt the fundus forward, thus aiding the action of the round ligaments. An anterior colporrhaphy is also performed when there is much anterior bulging. I find the use of the buried suture of great advantage in this operation as well as the form given the denuded surface. This mode of procedure may be old to others, though new to me. I have taken the liberty to describe it thus briefly in this paper, as I believe a colporrhaphy to be equally as important as Alexander's operation in all cases of procidentia, and also in cases of retroversion attended by vaginal subinvolution; and in the dozen cases in which I have used this method, I have found the results much more satisfactory than other methods which I had previously employed.

The expectation from Alexander's operation is not that the ligaments will permanently hold the uterus up, but that they will hold it forward for a sufficient length of time to allow the pelvic contents to rearrange themselves in normal positions; and if the natural supports of the organ can at the same time be restored, a cure will be accomplished; otherwise the patient will assuredly drift back, in

time, into the old condition. It is not the normal function of the round ligaments or muscles to sustain the uterus; but we have shown by experiment that their strength is amply sufficient to enable them to be used temporarily for this purpose. Nevertheless, no intelligent gynecologist would think of depending upon these frail muscular bands as a permanent support for both the uterus and a large part of the abdominal contents. I speak of this, not for the information of this audience, but as a defense against damaging impressions which I have found existing among physicians that Alexander's operation is claimed by its advocates to be a radical cure for procidentia and all its grave consequences.

3. As at least third in importance, I should rank the utility of this operation in the restoration to proper position of enlarged and prolapsed ovaries, when painful and a cause of serious reflex or local disturbance, irrespective of the position of the uterus itself. In forty-two of the forty-seven cases upon which I have operated, the ovaries have been prolapsed. In fifteen of these cases one or both prolapsed ovaries has been very much enlarged. In two instances the enlarged ovary was as large as a very large egg. In every instance, with barely two exceptions, the prolapsed ovaries have been so perfectly restored that they could not be felt in vaginal examination after the operation. The rescue of this sensitive organ from its perilous position—crowded down behind the uterus, exposed to the pressure of hardened feces and the jar of every misstep in walking, as well as the passive congestion due to the mechanical obstruction to its circulation, and its restoration to its normal and protected position, is in itself the first step, and the most important step, toward the restoration of the ovary to a normal condition in other respects. I am convinced that a very large part of the good results which I have seen from this operation should be attributed to the restoration of the ovaries to their normal position, rather than to the change in the position of the uterus.

The existence of antelexion or anteversion is not a contraindication for the operation, at least in my experience, if needed for the restoration of a prolapsed ovary. I have operated twice in cases in which this condition existed, without in the least degree aggravating the anterior displacement; and although it has been my uniform rule in operating to draw the ligaments out as far as possible without undue force, I have not produced a harmful degree of anteversion in a single instance.

4. I offer, as a fourth indication for this operation, extreme anteversion of the uterus when the patient suffers much from bladder disturbance. The results in the one case of this sort, first reported at the last meeting of this Association, have been all that could be desired, and I see no

reason why equally good results may not be obtained in other cases.

The operator who wishes to succeed with Alexander's operation, must not consider that when the operation is done, every thing has been accomplished. The shortening of the round ligaments should be regarded simply as a procedure for securing conditions favorable for the success of other means of treatment, which, without it, could not be permanently successful. I will briefly summarize what I believe to be the most essential features of the successful after-treatment of cases of this sort:

1. After the operation for the shortening of the ligaments, and the colporrhaphy or perineorrhaphy, or both, in cases requiring these operations, have been performed, a suitable pessary should be worn for six to twelve months, so as to remove all strain from the uterine ligaments and give them an opportunity to shorten, and prevent the round ligaments from being stretched to their original length. In my earlier cases, not appreciating the full value of the pessary in the after-treatment of these cases, I failed to obtain the best results in some cases which I believe would otherwise have been entirely successful.

2. The use of the vaginal douche for several months following the operation, I consider a very important means of aiding the contraction of the uterine ligaments and the return of the uterus and ovaries to their normal condition. Medicated pledgets of cotton may also be advantageously employed in many cases.

3. Another measure which I consider one of the most important of all in securing such a degree of improvement as will insure the patient against a speedy relapse into the former condition, is the correction of faulty modes of dress. It is not simply necessary to discard the corset, as I am satisfied that tight waist-bands and heavy skirts do more harm than do corsets. I have met many cases in which women who had discarded corsets, have injured themselves greatly by wearing numerous heavy skirts, drawn tight, and hanging upon the hips and lower abdomen. Skirt suspenders do not wholly remedy this evil, unless the skirt and dress bands are very loose; and every experienced physician knows that the average woman does not know when her clothing is loose. My rule is to make the patient take a full breath when the skirts and skirt-bands are loosened, take a measurement of the waist while the breath is held, with the lower portion of the chest expanded as much as possible, add one inch to this measurement, and adopt this as the standard measurement for skirt-bands and all clothing about the waist. I have made some measurements of the amount of downward pressure produced by corsets, waists, skirt-bands, and other articles of clothing, and in one instance found the column of mercury raised to twenty

inches during forced inspiration. This means a pressure equal to ten pounds per square inch. With such a pressure as this bearing downward upon the uterus and other pelvic organs, no permanent gain could be hoped for by means of Alexander's or any other operation, unless it be that of attaching the fundus of the uterus to the anterior abdominal wall.

4. Lastly, as another most important means for the prevention of a relapse into old conditions after this operation, may be mentioned electricity and massage, and such special active and passive exercises as will strengthen and develop the abdominal muscles and the normal supports of the uterus and other pelvic viscera. For a dozen years, I have employed electricity extensively in the treatment of uterine displacements of various sorts, sometimes with very satisfactory results, at other times without apparent effect in the direction of the improvement of displacements. Combining this agent with Alexander's operation as a supplementary therapeutic means, affords a more favorable opportunity for good results.

I have employed different forms of currents, the faradic current, the slowly interrupted galvanic current, the galvanic and faradic currents combined, and the dynamic current. The latter current, supplied by a small machine giving a reversing current, I have found the most effective of all means of stimulating contraction in the muscular structures which support the uterus. When one electrode is placed upon the abdomen and the other in the vagina, energetic and painless contractions are produced in the abdominal muscles, the sphincter muscles of the rectum and vagina, and the other muscular structures within the pelvic cavity. Experiments made with this current on a patient under ether and with the round ligaments exposed and isolated, showed contraction of these structures also when the electrodes were applied as indicated. If it be true, as has been suggested, that other of the ligaments of the uterus as well as the round ligaments, are to a considerable degree, muscular in their structure, I deem it wholly probable that these also participate in the contraction. These contractions occur at every reversal of the current, so that this current not only has the effect to stimulate nutritive changes in the diseased structures, but also affords a most valuable means of securing functional activity in idle and relaxed parts, thus giving them the benefit of a genuine gymnastic exercise. The therapeutic results following the use of this current justify me in claiming for it a decided superiority over any other form of electrical current for this purpose. I have used this current for medical purposes for the last five years, and in the after-treatment of cases in which the round ligaments have been shortened during the last year.

Massage, combined with faradic electricity ap-

plied in such a manner as to secure contraction of individual muscles and groups of muscles, is also a measure of great service, not only in securing the general improvement of the patient, but more directly, when localized in its application, as a means of strengthening the abdominal muscles and aiding the readjustment of the abdominal viscera to a normal condition. Massage is also a most potent means of relieving the obstinate constipation with which a large proportion of persons requiring this operation habitually suffer, and which will almost certainly occasion a recurrence of the displacement unless relieved.

Light calisthenics, exercises with Indian clubs and dumb-bells, pulley weights, etc., are of essential service. In fact, a regular systematic course of physical culture, or appropriate gymnasium training, is, in my opinion, necessary to fully insure a woman who has once suffered from uterine displacements from an ultimate recurrence of the condition. These patients often have an original defect in organization, a lack of physical development, or at any rate of a symmetrical development which predisposes them to uterine displacements. A young woman who has failed to develop strong abdominal muscles, who has not been allowed to run, jump and romp, and harden the muscles of the trunk and limbs when a girl, is a candidate for retroversion or flexion, or ovarian prolapse, or some allied malady as soon as she is obliged to endure any sort of physical hardship. This is, in my opinion, the reason why so many young women attribute all their ailments to going up and down stairs at school. I see no reason why a woman may not go up and down stairs as well as a man if her muscles are properly developed. Stanley asserts that the strongest porters in some portions of Africa are women. Inquiry in the hospitals of France, Germany, and Italy convinced me that uterine displacements are much less common among the women of the laboring classes of that country than in this country. If then, we have performed the operation of shortening the ligaments upon a woman whose physical development has been neglected, we must not be content with making her as well as before the displacement occurred; we must make her better than before, or the same morbid conditions will follow the same causes. If, then, instead of sending away a patient upon whom the operation of shortening the ligaments has been performed, with the same weak and unbalanced muscular condition as before, we subject her to a series of carefully graded exercises by which weak parts are strengthened and feeble parts developed, we prepare her to endure without injury those physical hardships, muscular strains, etc., which she must necessarily encounter, and thus insure her against the relapse which otherwise will almost inevitably occur.

Pursuing this plan in the management of cases upon which Alexander's operation has been per-

formed, I am sure that radical cures may be effected in numerous cases which by other means could only be palliated. As an essential aid to curative gynecology, I believe this operation is destined to prove a most valuable addition to this branch of medicine; and I feel confident that its proper employment in conjunction with other measures of treatment, and especially the appropriate after-treatment of cases, will in due time wear away the prejudice which has arisen against the operation through the neglect of the use of the supplementary measures necessary to secure to the patient operated upon the great benefits which might otherwise have been secured.

[Since the above paper was written I have performed the same operation in twenty-two additional cases, making sixty-nine in all. At the present date I find in the total number but four failures, ten much improved, and fifty-five complete successes. Of the last forty cases, there has been failure in but one case, and this was due to an accident in which the patient was led to exert herself so violently just after getting upon her feet subsequent to the operation, that the ligaments were torn loose. The total percentage of successes, including my first series of twenty-nine cases by the old method, is eighty. J. H. K.]

NASO-PHARYNGEAL FIBROMATA.

Read in the Section on Laryngology at the Thirty-ninth Annual Meeting of the American Medical Association, Cincinnati, May, 1888.

BY E. FLETCHER INGALS, A.M., M.D.,

PROFESSOR OF LARYNGOLOGY, RUSH MEDICAL COLLEGE; PROFESSOR OF DISEASES OF THE THROAT AND CHEST, WOMAN'S MEDICAL COLLEGE, CHICAGO.

In 1884 I presented to this section a paper on naso-pharyngeal fibromata in which I reported four cases, two of which had been cured, and two of which had disappeared so that the result was unknown. In that paper I advocated the extirpation of these growths, when possible, through the natural passages by means of the galvano-cautery *écraseur* or other methods, employed by laryngologists in the destruction of nasal polypi, in preference to the formidable operation including removal of the superior maxilla, which has frequently been practiced by surgeons, and which is still believed, by some, to be the best means of eradicating these growths.

In a paper by Dr. Lincoln, of New York, to which I referred in my former article, it was shown that the operation usually adopted by surgeons was extremely hazardous—over 25 per cent. dying from the operation, while it was not very successful in preventing recurrence, as in only about 14 per cent. was it certain that the tumor had not returned within a year. By the method which I then recommended it was shown that the danger to life was very much less, and that the ultimate results were much better, as in

over 50 per cent. of the cases recurrence had not taken place within twelve months.

Recently one of the cases then reported, which had failed to return after the first sitting for completion of the operation, and which I had lost sight of at the time my former paper was written, has returned to me after the lapse of five years with a renewed growth in the same locality. This I have removed by means of the galvano-cautery *écraseur* at my clinic at Rush Medical College, in presence of Drs. Hinde and Breckinridge and the medical class. The operation was done after the parts had been anesthetized by cocaine, and was completely successful in the removal of all of the tumor. It consisted of three lobules which had been attached by a base about half an inch in diameter at the vault of the pharynx and posterior naris of the left side. The tumor removed five years ago had the appearance of being composed entirely of fibrous tissue. Of the tumor recently removed the smaller lobule, which measured about five-eighths of an inch in diameter, proved upon microscopic examination, made in the Physiological Laboratory of Rush Medical College, to be made up of fibrous and cellular elements, being about four-fifths fibrous.¹ The next larger lobule which measured about three-eighths inch in diameter by one and a half inch in length, appeared to be fibro-cellular in character about one-half fibrous, and the largest which measured about one by two inches in diameter, seemed also fibro-cellular, about three-fourths fibrous. This case was at first reported as fibrous, and I believe that the tumor first removed fully justified placing it in that class, though the recent growths contain more of the cellular elements than is usual in the true fibromas. In this case there has been a recurrence of the growth as I had expected, because it was not entirely removed at first, the patient having failed to present herself for the second operation; but its slow growth, and the fact that these tumors are less likely to recur at this patient's age than in subjects at about the age of puberty, leads me to hope that the recent operation may prove the last one necessary.

I have also to present to the Section the history of a case from which I recently removed a large fibrous growth from the naso-pharynx with the galvano-cautery.

The patient, W. K., *æ*t. 16, was brought to me by Dr. White, of Sandwich, Ill. I found that for two years he had been troubled with difficulty in breathing through the nose, and frequent epistaxis. For about two months before consulting me he had suffered from frequent alarming hemorrhages, during one of which Dr. White had been called in for the first time. The doctor checked the hemorrhage, but the patient was much exsanguinated and in no condition for an

¹ This was examined by Mr. Frank Lyman, 1st assistant in the physiological laboratory.

immediate operation, therefore, he was placed on tonics and nutritious food and given time to recuperate. As a result I found the patient well nourished and with no appearance of anæmia. His voice was of that peculiar character known as nasal, the sense of smell was nearly lost, and he complained of pain in the side and back of the head. The left cheek over the lower maxilla was quite prominent, and apparently swollen, but there was no induration excepting just opposite the posterior molar of the upper jaw, where a conical tumor could be felt deep in the soft tissues. This tumor appeared to be about five-eighths of an inch in diameter, at the farthest point where it could be felt, which was about the same distance back of its apex, and it was evidently attached far back in the tissues, out of reach. Upon examining the nares anteriorly, I found the posterior third of the left cavity filled with a firm growth of a light pink color, which bled very easily on being touched with a probe. Examining the mouth I found the soft palate crowded downward, and upon a rhinoscopic examination discovered the naso-pharyngeal cavity to be filled with a tumor of a light red color, and smooth surface, which was found to be hard to the touch. The slow progress of this case, the frequent attacks of epistaxis, and the appearance of the growth itself, convinced me that it was a fibroma. I recommended removal by the galvano-cautery *écraseur*, and left the patient to decide whether it should be done under the influence of cocaine or ether. I much preferred the former, knowing that with it, I would have a much better view of my work, yet I feared from experience with other cases that he might suffer considerable pain. Being anxious to return to his home as soon as possible, he decided to submit to the operation with only such relief from pain as could be afforded by cocaine. On the afternoon of the same day I operated, with the assistance of Drs. J. E. Rhodes and White and Mr. J. A. Bauchman. A 10 per cent. solution of cocaine was first applied to the naso-pharynx and left naris by means of an atomizer and syringe about once in two minutes, for fifteen minutes, until the parts were benumbed. I then passed through the left naris two catheters which were brought out of the mouth and through them passed the two ends of a No. 8 platinum wire. As these were drawn out the nostril with the catheter the loop was carried up behind the tumor by the finger. The ends of the wire were then passed through a tubular electrode, made fast to a ratchet on the handle, and the battery was connected. I then tightened the loop by turning the ratchet, and heated the wire for two or three seconds by closing the circuit, then allowed the patient to rest a few seconds, and then repeated the procedure, thus alternately heating the wire as long as the patient could easily bear it, and then allowing it to cool

and tightening the ratchet. I soon burned off the growth, at its base, which was more than an inch in diameter.

The tumor was removed through the mouth and proved to be a fibrous growth measuring $1\frac{3}{4}$ by 2 inches in diameter, and 1 inch in thickness.

The operation had been easily borne, though it would have caused much pain if I had kept the wire constantly hot until the base of the tumor had been severed. Thus far there had been no bleeding. I then found that a portion of the growth still remained in the posterior part of the left naris. I could not engage it in a snare and therefore attempted to remove it with cutting forceps, but immediately profuse hemorrhage occurred, and I was obliged to plug the nose with a strip of gauze saturated with a thick mixture of tannic acid. This checked the bleeding promptly, but the patient had lost about a pint of blood in five minutes, and therefore further operations were deferred. The patient returned to his home the same day and no unfavorable symptoms recurred. Three weeks later he came to me again. The tumor within the nares had somewhat increased in size and was then found to be of such a shape that it could not be engaged in the snare, therefore I adopted a method which had been successfully employed in a few cases of this kind. I applied cocaine to the tumor in the nares, then introduced into it an electrolysis needle which I connected with the negative pole of a galvanic battery, applying the positive pole at the same time by means of a large flat sponge to the angle of the jaw and side of the neck. I turned on as many cells as the patient could tolerate and continued the electrolysis for fifteen minutes. Ten days later the patient returned and I found that the electrolysis had very materially reduced the size of the tumor, but at this visit I was able to remove a mass about half an inch in diameter with the galvano-cautery snare, therefore did not use electrolysis. Two weeks later I found that the small tumor in the cheek was reduced to one-fourth its former size. I again used the galvano-cautery snare, and removed a small portion of the tumor, and at the same time seared the surface of what remained in the naris. I was unable to remove enough of the growth to allow of free nasal respiration. About two weeks later the patient again returned. At this time I was unable to feel anything of the tumor in the cheek, and all the growth appeared to have been removed from the naso-pharynx, excepting a small mass at the opening of the left naris. The patient could breathe through the left naris considerably, but still a portion of the tumor obstructed its posterior part. I again practiced electrolysis. Ten days later the patient returned having progressed favorably. He was able to breathe through the left naris much better than formerly. Used electrolysis again.

During the past three years I have operated on two other cases of naso-pharyngeal tumors which appeared at first to be simple fibromas. The first case, A. P., æt. 13, was brought to me from Dakota, and during the course of a year and a half underwent three distinct operations, in each of which the tumor was removed as thoroughly as possible, but a portion of it which had become involved in the tissues about the pterygoid process of the sphenoid and a portion which passed into the cheek, could not be extirpated. The late Prof. Moses Gunn at one time removed the tumor from this patient's cheek; the tumor was about an inch in diameter. During the last six months of the treatment the naso-pharyngeal tumor grew so slowly that I hoped for its complete destruction, but the boy, who was in the city without friends, fell into bad company, and I felt compelled to send him home while a small portion of the growth remained. I have not since heard of the case.

The second of these cases, E. I., aged about thirteen, was brought to me from Nebraska about two and a half years ago, with a fibrous tumor which filled the left naris and naso-pharyngeal cavity. In this case the tumor was removed, partly by the galvanic cauterizer and the steel wire *écraseur* and partly by cutting forceps. There was profuse bleeding whenever the cutting forceps were used, but it was readily checked by plugging the nasal and naso-pharyngeal cavities with a strip of gauze saturated with a mixture of tannic and gallic acids which had been rubbed up with just enough water to make it the consistency of syrup. The record of the case has been lost, but I recollect that three or four operations were done at intervals of from three to five months. Each time the growth being removed as completely as possible, though a small portion of it was doubtless left in the tissues about the pterygoid process. The last operation was done about a year ago, and I have not since heard directly from the patient whose residence I do not know. But from another patient who knew of the case, I heard recently that the boy is living and that so far as the friends can tell the growth had not returned. Though I am not certain of the result in either of these cases, I believe that it promised to be better than could have been expected from a more formidable operation.

These cases I have reported merely as an addition to the literature of this interesting subject, and with the hope of eliciting discussion which may be of much value. In the present state of our science, I believe that all of these cases which afford any reasonable hope of cure should be operated upon through the natural passages. When the tumor has been removed, if any parts remain which are inaccessible to the *écraseur*, cauterizer knife or cutting forceps, they should be treated by electrolysis, and thus even if we fail to

at once eradicate the growth we may hope to prolong the history of the case to the period of adolescence, at which time nature seems to set a limit, at least in many cases, to the further development of these growths, and then a cure may be effected.

70 State Street, Chicago.

FETICIDE AND ITS PREVENTION.

Read in the Section on Medical Jurisprudence, at the Thirty-ninth Annual Meeting of the American Medical Association, May, 1888.

BY H. C. MARKHAM, M.D.,

OF INDEPENDENCE, IOWA.

In approaching the consideration of the subject of feticide we are at the outset confronted by two facts, both of which possess an important significance. We first note that the highest crime—from some standpoints at least—of which criminal humanity is capable, and whose prevalence doubtless exceeds the highest estimate, is of no more judicial importance, in either treatise or statute, than when the evil was scarcely known, and motherhood was everywhere the crowning glory of woman. The second fact is little less an anomaly: that in the presence and despite the elevation, culture, refinement and, more than all else, the religious training and influences operating upon and in modern social life, that in the class of society making in all these respects the highest claims, this vice has developed, the enormity and extent of which is but feebly recognized outside the medical profession.

As aiding our purpose, which is that of endeavoring to discover remedies for the repression, if not suppression, of the crime of offspring murder, it may be useful to attempt an explanation of the causes whose operation has given this crime its peculiar status or, it may be said, have prevented its having any proper legal status in the calendar of capital crimes. So intimately blended and associated are the moral, judicial and medical phases of feticide, that its relegation to the especial realm of either the law, the church, or medicine, has never been satisfactorily agreed upon. As neither profession has felt the obligation or responsibility concerning the evil which otherwise would exist, the evil, therefore, has naturally failed to receive in any proper degree an adequate consideration. To the moralist and jurist it presents a barrier of delicacy whose sacred realm they instinctively shrink from invading. The resistless power, also, of social pride and ambition would seem to leave little hope of reform through moral agencies. The highest level of ethical profession, in the geography of the modern social world, is honeycombed by this lurking and hideous evil. The conditions insuring perfect concealment and the absolute certainty of the ignorance of the public as to its commission impart characteristics both unique and formidable to the crime. Feticide is

also the one great crime in which the chief victim, or sufferer, is wholly defenseless and without hope of an advocate. The type of unresisting innocence, it possesses no posthumous resources whose magic wand may set in relentless pursuit of the guilty the instruments of justice.

The champions of the temperance cause, in order to enforce and prove their claims, have only to point to the living victims of dissipation. Those espousing the cause of social purity easily refer to living illustrations of the evils they seek to remove. Statistics are the weapons most feared by the foes of public good. But fœticide enjoys immunity from all these methods of attack. As this important subject is, for inherent reasons, unsuited for judicial investigation, and successfully opposes religious influences, the obligation necessarily rests upon the medical profession to propose a method for checking the fearful progress of the evil. It scarcely subverts the purposes of this paper to attempt a delineation of the diabolical attributes and features of the crime from a moral standpoint, or to essay a medical statement and description of results, both pathological and physiological, of its committal. Neither is it essential, however *apropos* it may be to the discussion, to note its social relations; how the resistless lust for fashionable dissipation and distinction has rendered barrenness essential to their gratification. The limitations of time compel here an omission of these phases of the subject, however much they deserve that attention hitherto unreceived.

Judicially viewed, fœticide has characteristics and relations which render its treatment not only delicate but difficult. Of no other crime is it true that in nearly every instance of its commission there exists ample and unimpeachable evidence of the same, which evidence is also both vital and unavailable. Until a change occurs as to the application of professional rules and tenets in giving evidence in this class of cases, there is little ground for expecting success in the prosecution of the same. Refusing to be used as witnesses to aid the State in punishing those guilty is in contravention of the chief mission of medical science, which is no less than the removal of the causes of physical degeneracy and vice. The position of medical men as witnesses in cases of fœticide is for this reason exceptional, not compelling him, as in other cases, to defend the precepts of his profession and the rights of his patients by refusing to disclose the secrets and confidence of the latter.

Fœticide no more entitles the patient to this secrecy and confidence than does small-pox or other danger to the public, the stamping out of which is the duty of medicine to perform—*per contra*, it as greatly obligates the disclosure of the same. Is it not to be feared that the assurance of medical aid and confidence if danger follows operates as a strong incentive to attempt the performance of the crime upon themselves by those de-

siring it—a practice which the profession well knows is rapidly increasing. Probably no fact is indirectly more promotive of fœticide than the absence of laws regulating medical practice; thereby enabling abortionists, disguised as members of an honorable profession, to pursue their nefarious avocation with comparative impunity. Nothing less than adultery itself can exceed the wrong inflicted upon the husband who suffers wilful betrayal of his hopes and expectations of offspring. If congenital, and hence irresponsible physical procreative incompetency is adequate cause for legal dissolution of marital relations, how much more—measured by every possible standard—is the intentional procurement of the misfortune. Added to this loss is the keenness of disappointment which near realization tends to induce. Medical men will verify this as being no fancy or rare event, as too frequently, when called to rescue the victim from her self-induced peril, has it been a duty to impart to the anxious husband the cause of the danger and the first knowledge of his already severe loss.

Fœticide as a ground for divorce of either party to the marriage contract; whether it result from guilt of the wife, on the one hand, against the wishes of the husband, or whether the husband compels the unwilling submission of the wife to its procurement, upon the other, is, in either instance, both just and practical. Penalties aimed at "abortionists" as a class of criminals are little less than valueless. The party inciting the act—its actual principal—must be made to fear the consequences. The question is worthy the most serious consideration, whether the present facilities, and the alarming extent of their improvement, for disseminating criminal knowledge of the practice, does not remove the usual objections to a popular presentation of the evil as such. That once thought unsuitable for general publicity, is now sown widely by the vultures who fatten upon the harvests.

Our young men are properly taught the evil effects of alcoholic excess—why should not young women be warned of the nature and results of fœticide? There can be, from thoughtful students of the subject, only an affirmative reply. The task of the performance of this duty rests upon the medical profession, and every prompting of interest in the welfare of our race induces the hope that medicine may not betray the trust.

Independence, Ia., April 23, 1888.

THE ARNOT-OGDEN MEMORIAL HOSPITAL, of Elmira, N. Y., the gift of Mrs. Ogden to the city of Elmira, will be completed, at a cost of about \$100,000. The buildings are of brick, and it is said that the most approved methods of sanitary engineering have been employed.

PSEUDO-HYPERTROPHIC MUSCULAR PARALYSIS.

Read before the Indiana State Medical Society, June, 1888.

BY W. BYFORD RYAN, M.D.,
OF WILLOW BRANCH, IND.

I have the honor to present for your inspection three persons afflicted with this rare and imperfectly known disease.

The disease was first described by Sir Charles Bell in 1830; by two Italians, Coste and Gioja in 1838; by Meryon in 1851. The disease did not, however, receive much attention until Duchenne (of Boulogne) reported his collection of thirteen cases in 1868. The same year Dr. Meredith Clymer described the disease under the title "Progressive Myo-Sclerotic Paralysis," though he had not probably at that time seen a case. Dr. Clymer seems inclined to attribute the honor of discovery and first description of the disease to Dr. Edward Meryon, whose paper "On Granular and Fatty Degeneration of the Voluntary Muscles" was read December 9, 1851, and published in the *Medico-Chirurgical Transactions*, Vol. xxxv, 1852.

"Dr. Duchenne (de Boulogne), scouts the idea of Dr. Meryon having first described this affection (*la priorité de la découverte*). 'L'honneur de cette découverte appartient tout entière à la France' (that is, to himself). In the same paper he says: 'La découverte de la paralysie pseudo-hypertrophique remonte à l'année, 1858,' the year he observed his first case. Thus, by his own dates he admits Meryon's priority in description.

Up to 1867 there were less than fifty recorded cases in the Old World and none on this side of the Atlantic. Subsequently Ingall and Webber, Pepper, Weir Mitchell, Hamilton, and others have reported cases. More recently Gowers, in a clinical lecture in London, 1879, carefully reviewed the cases of English, Continental and American writers and compiled reports of one hundred and seventy-six cases. Of these all but eight were children. This seems to be the entire number on record to that date. I add four cases, three children and one adult.

It is not my purpose to enter into a verbose description of the disease, for excellent descriptions may be found in Clymer's Appendix to Aitken's *Science and Practice of Medicine*; in Ross's *Diseases of the Nervous System*; Pepper's and A. McL. Hamilton's works. Neither shall I attempt to solve the problem relative to the primary seat of the lesion, whether it be the muscles themselves, the anterior columns of the cord, or the anterior roots of the spinal nerves; but I shall confine myself to the history of the cases before us, presenting to you the characteristic appearance, attitude and pathognomonic actions of persons so afflicted, in a manner so definite that those

who see need have no difficulty in recognizing the disease if so unfortunate as to meet it in practice.

Dr. Duchenne details the symptoms of the disease in the following order:

1. In the beginning feebleness of the lower limbs.
2. Lateral balancing of the trunk and widening of the legs during walking.
3. A peculiar curvature of the spine or saddle-back in walking and standing (I may add in sitting).
4. Talipes equinus with an over-extension of the first phalanges of the toes.
5. Apparent hypertrophy of muscles.
6. Stationary condition.
7. Generalization and aggravation of the paralysis.

These are the striking features of the disease as I have observed it; and I may add the 8th, which is not, however, characteristic, atrophy of affected muscles.

The family to which these boys belong consisted of four boys and one girl. The eldest son, whom we have before us, is seventeen years old.

No. 1. Walter.

He began to walk at fifteen months, was always awkward, and kept a very unstable equilibrium. He received many falls which an active child would have escaped, and many reprimands from his parents for being "lubberly" and inattentive, before they realized that all this came of weakness and partial paralysis.

His general health has always been excellent. Has never had pain in affected muscles, febrile symptoms, convulsions, or any prodromata. He was a well-formed child, and the hypertrophy of his calves was marked by all observers, and, to his friends, added to the symmetry of his limbs. His appetite was unusually keen, even for a growing boy, and, though vast quantities of excellent food and almost an equal amount of condiments and other "trash" was consumed between meals,

his digestion never seemed to suffer. He was a gourmand, and still has an excellent appetite.

At nine years the sacro-lumbar curvature was very marked. This attitude is assumed because of weakness of the dorsal muscles and is essential to the maintenance of the erect posture.

The increasing cordosis led the family to call a prominent physician, a member of this Society, residing in an adjoining county, to consult with the gentleman who, up to this time, had been the family physician. I do not know what was the diagnosis. A plaster jacket was proposed, but for some reason never applied. Treatment of beef, wine and iron, and of hypophosphites of lime and soda was given and persisted in for six months. No improvement followed, but, on the contrary, the disease progressed.

The patient, discouraged and disgusted with treatment of any kind, came under my care. After careful study, I diagnosed pseudo-hypertrophic muscular paralysis, and gave an unfavorable prognosis. At this time I had seen no literature on the subject except Dr. Clymer's article in Aitken's Practice.

Strictest regimen and a large curtailment of the bill of fare was enjoined. An effort was made to tone the nervous system by the administration of bark, iron and strychnia; but Fowler's solution and regimen were the means in which I had most faith. Having no battery at hand, faradization was not tried. The patient made some improvement. He was able to ascend two or three steps; could stoop and again assume the erect posture by simply placing one hand upon the knee instead of climbing with the hands up the legs as you see Herbert, his younger brother, do. (See cut No. 2.)

The restrictions as to diet were disregarded, because the boy's insatiable appetite could not be curbed by indulgent parents and good-natured servants. The patient petulantly protested against taking remedial agents, and the parents yielding to him, treatment was discontinued after less than two months' trial. At this time the boy, now near ten years old weighed 120 pounds. Within three months of the time he came under my care he was sent, against my protest, to the Surgical Institute in this city, where he was put upon the rack and his enfeebled muscles exhausted by enforced exercise. A brace was strapped upon him for the correction of the spinal curvature which is, as before stated, voluntarily or intuitively assumed as a compensatory relief of the enfeebled dorsal and lumbar muscles. After spending near six months in the institute, he returned to his home almost deprived of the power of locomotion, and within a few weeks he took to his chair, from which he has not arisen unaided since. He has been unable to walk or even to stand since he was eleven years old. At thirteen years he weighed 140 pounds, but since that time he has lost by

atrophy what he had gained by hypertrophy. The gastrocnemii are in permanent contraction. The disease has progressed very slowly since he took to his chair. He has not been treated for this affection since his return from the institute in this city. The muscles of the arms, back and shoulders are atrophied and powerless; but he derives much comfort and some profit from the use of the muscles of the forearm and hand, which are still subject to his will and retain a degree of force. The grasp is feeble yet he writes a beautiful, uniform hand. The abdominal, intercostal and sphincter muscles, and those of the face, throat and diaphragm seem to be intact. His mind is clear, memory good. He stands fair in his classes at school and, though not unusually quick, he is, in mathematics, rather better than most of his associates in this department. He expresses an earnest desire to have the progress of the disease arrested at this stage, and says that if he could remain as he is life would be enjoyable rather than burdensome to him.

The second son of this family never had any perceptible symptoms of this disease. He began to walk at twenty-one months; was intellectually clear though not brilliant; was peculiarly reticent and old in his ways though active in movement. He had a severe attack of rheumatism, which came upon him suddenly, making him helpless, one day at school. Whether this attack meant anything more than rheumatism I cannot say; yet, in the light of subsequent developments in this family, the presumption is strong that the disease under discussion entered as an important element. Urinary tests, however, and the usual treatment demonstrated the correctness of the diagnosis of rheumatism. There were cardiac complications. His chest was his vulnerable point in the opinion of his parents and former physician, and I acquiesced in that opinion long before this illness. When the more violent symptoms of rheumatism subsided a pulmonary trouble, which I then regarded as tuberculosis, terminated his life at the age of nine years. I have since thought that the lung affection would not so soon have carried him off had not paralysis of the diaphragm entered as a factor; but this is an after-thought and somewhat in the nature of speculation.

The third child, a blooming girl of ten years, is sprightly, healthy and mentally bright. I have no fears of her being affected, with this disease for the reasons that there are no indications of it, and the disease is almost, if not entirely confined to the male sex. Yet it is more than probable that she will transmit the disease, as the transmission has, hitherto, always been through the maternal ancestors.

The fourth child, a son, Herbert T., is before you. (See fig. 2.) He walked at thirteen months.

It is needless to say that he is progressing more rapidly in his decline with this terrible malady than did his elder brother. He is eight years old. You observe the attitude he is compelled to assume in order to maintain his equilibrium, and his shambling gait, peculiar in the pitching the feet forward with the toes lower than the heels, the latter being the beginning of an equinism produced by permanent shortening of the gastrocnemii and paralysis of the extensors. Your attention is invited to the size of his calves and to their firmness to the touch; myo-sclerotic paralysis is not a misnomer. Observe that the muscles of the thighs, arms and back are beginning to atrophy. This boy, aside from this disease, has always had excellent health, a sharp appetite and a good digestion.

No. 2. Herbert.

I desire to call your attention to his method of arising from the sitting or stooping posture. (See cut 2.) He will not permit one to lift him into the standing position, for the reason that he would fall forward if deprived of support before he was able to curve his spine into the peculiar saddle-back pose, with abdomen thrown forward and shoulders back. In order to attain the position given in cut No. 2, arising from the ground, he first gets upon hands and knees, then grasps his ankles, then climbs his legs with his hands. Having attained the position given in the cut the next act is to extend the knees, which is effected by bending forward and downward, so as to cast the center of gravity in front of the knees, the weight acting as the power at the hip joint, extending the knees without the use of the quadriceps extensor. To extend the hip joints the patient works his way up the thighs, placing his

hands higher and higher until the erect posture is attained, the shoulders are cast back till the arms swing so far back that the hands drop back of the pelvis. This behavior in arising from the ground is striking and pathognomonic. Sir Charles Bell recognized it and declared that it is met in no other disease. Gowers and Hamilton are of the same opinion.

The youngest child, who is before you, a boy named Raymond T., is 3 years old. Has been healthy in the main. Had an attack of pneumonia last winter attended with great cerebral disturbance but no convulsions. He is clumsy, maintains the attitude of his brother Herbert in a less pronounced degree, and evidently will follow the pathway of his brothers, unless haply something can be done to avert this calamity.

The heads of these three boys are unusually large.

The eldest, Walter, æt. 17 years, circumference of head $23\frac{1}{2}$ inches.

The third son, Herbert, æt. 8, circumference of head $21\frac{1}{8}$ inches.

The youngest, Raymond, æt. 3 years, circumference of head $21\frac{1}{2}$ inches.

So far as I have been able to learn there is no history of pseudo-hypertrophic muscular paralysis in the family of the mother of our patients. Her mother, who is still living and active, is now 70 years of age.

The paternal grandfather, æt. 76, is, undoubtedly, a subject of the disease, though he vindictively repudiates such an intimation, and, while he acknowledges that his back is weak and his arms and shoulders are not what they ought to be, he attributes his weakness and awkwardness to age, the effect of erysipelas and a fall received many years ago. From the best information I can get, the disease began to show itself in him after a traumatic lesion, and has progressed very slowly, though I cannot bring myself to believe that the disease originated in the traumatism, received after the age of 50. I regard the traumatism as the means of arousing the latent disease. About a month ago the old gentleman, after a ride of 22 miles, sat down to a very late dinner, and on attempting to arise from his chair, fell heavily to the floor, and was unable to arise for nearly one-half hour, declining help. This fall was followed by some fever and considerable mental agitation, a kind of talkative delirium for two or three days, after which he was, and is, as well in every respect as usual. The muscles of his back, thighs and arms are considerably atrophied, yet he is by no means so disabled as either of the grandsons shown you to-day.

There are two things unique in this case:

1. Development of the disease at an advanced age of perhaps 50 years.

2. Hereditary transmission through a son. Hitherto it has been only on the mother's side

that the hereditary influence has been transmitted, while the disease develops almost invariably in males. Several brothers of the old gentleman died of phthisis pulmonalis; one died of some renal disease, probably diabetes mellitus, one sister had a slight paralytic seizure, but is fully recovered. All his brothers and sisters have lived to advanced age save one.

The boys shown you to-day have two uncles and an aunt on the father's side who are married and have children; but as yet none of these cousins, six in number, four males and two females, have shown symptoms of this disease, though two are fathers and two others have reached puberty. In conclusion, I ought to say, that there is not a male member of the grandfather's family or of his nephew's, with whom I am acquainted, whom I would regard as an active man, though they are energetic and of average strength.

HYSTERIA OF A GRAVE FORM IN THREE SUCCESSIVE PREGNANCIES. CASE.

Read before the Medical Society of the District of Columbia, June 6, 1888.

BY ERNEST F. KING, A.M., M.D.,
OF WASHINGTON, D. C.

On Sunday, December 20, 1885, I was sent for to see Mrs. X., æt. 19, then in the fourth month of her first pregnancy. I found her having sharp uterine pains every ten to fifteen minutes. She had been, as she declared, "unusually well" during the previous months, and could assign no cause for the threatened mischief. Upon the administration of opiates the pains ceased and there was no further trouble for about three weeks. At this time a train of symptoms began which continued throughout the pregnancy. Mrs. X. went to bed, refused food, seemingly did not recognize any of the family, threw herself from side to side, moaning constantly—in short, went through every manœuvre that an hysterical brain could contrive. This would continue for four or five days, and would be followed by an interval of about the same duration when the patient would appear like herself. Every expedient suggested for such cases was made trial of, but without permanent benefit. Tonics were administered throughout.

On Friday, June 4, labor began. The day before violent motions of the child were felt, which suddenly stopped. The os dilated slowly, the pains were infrequent and short. Sunday morning, the patient beginning to become exhausted, I applied the forceps and delivered a well-formed dead child. The mother almost immediately became as a different person. Within a week her form rounded out, color returned to her cheeks, and she declared that she "never felt better."

I saw Mrs. X. at intervals during the months following, and some time in November learned

that she was again pregnant. She experienced no discomfort and appeared as usual. On February 15, 1887, she went down town on a shopping expedition, and while lunching at a restaurant felt a sharp pain. She walked to her home, some nine blocks, and went to bed. I saw her within an hour after her return and found her having pains regularly. A foot protruded from the uterus, and in a short time the labor was completed. There were no unfavorable symptoms, and the following day a desire was expressed to go back and finish the lunch.

Both Mrs. X. and her husband were greatly disappointed at the result of these pregnancies, having experienced much pleasure in the anticipation of offspring. In April I learned that the third pregnancy dated from the first of March. On July 7 Mrs. X. came to my office complaining of slight pains at long intervals. I advised rest in bed and, when afterwards the pains increased in frequency, I ordered full doses of opium, which effectually controlled the difficulty. At this time began again the train of symptoms observed during the first pregnancy. There would be periods, lasting for days, of hysterical manifestations with intervals of quiet. There was a constant change of symptoms. No two attacks were exactly alike, though there were points of resemblance, such as taking no notice of what went on in the room, refusing to answer questions, complaining of her head, and refusing to touch food. However, food left in the room frequently disappeared.

Once there was complaint of numbness in one arm and inability to use the same. She was seen through a partially opened door to be fanning herself, using the paralyzed arm, but at the noise made in opening the door the arm dropped as though powerless. In October came a new trouble. Every few minutes the diaphragm would violently contract three or four times. Mrs. X. declared that the motions were those of the child. Aside from these movements she appeared natural. At this time Dr. Jos. Taber Johnson saw her with me.

In November there were two periods when she became violent and I feared she would harm herself or the child. She passed safely through these, however, and on December 5, 1887, she was safely delivered of a well developed male child. With the same elasticity before displayed she was immediately herself, grew strong rapidly, and is to-day in the best of spirits.

Briefly stated, Mrs. X. has been pregnant three times. Each time there has been no trouble up to the fourth month. At this period she miscarried once, and there was evidently danger of the same the other times. After the fourth month was completed the first and third pregnancies presented the same train of hysterical symptoms accompanied by weakness, pallor, loss of flesh and constipation. The urine, though carefully exam-

ined at intervals, gave no trace of albumin. Nothing afforded more than temporary relief. A blister to the back of her neck gave good results; the discomfort seemed to cause her to forget her ordinary troubles. A strong interrupted current would likewise hold her attention.

Since December I have seen Mrs. X. frequently, and have noticed nothing unusual save a slight 'witching of the shoulder. A former servant of her mother tells me that Mrs. X. had "spells" at each monthly period while she was still in school. During these spells she would moan and throw herself about, not noticing others in the room.

During the past six months I have attended a brother and three sisters of Mrs. X., all of whom presented nervous symptoms entirely incommensurate with the cause of the trouble.

The case is of particular interest to me at present, for, since writing the above, I have learned that Mrs. X. is again pregnant, or at least she believes that she is, dating from April 1. Granting that she is, is it not probable that there will be some disturbance at the fourth month? If *this* trouble is overcome, will there not follow the same train of nervous symptoms that I have described?

HOSPITAL REPORTS.

Woman's Clinic, Cincinnati College of Medicine and Surgery.

SERVICE OF PROFESSOR CHARLES A. L. REED.

VESICO-VAGINAL FISTULA CONSEQUENT UPON VAGINAL HYSTERECTOMY. MODIFICATION OF TAIT'S OPERATION. RECOVERY.

Mrs. M., æt. 34, submitted to vaginal hysterectomy for carcinoma of the uterus in February last. The uterus at the time was found to be much enlarged, and was intimately adherent to the bladder for over three and a half inches. In the act of enucleation the bladder was accidentally entered and a fistula as large as a silver dime resulted. It was not, strictly speaking, a vesico-vaginal, but rather a vesico-abdominal, fistula, as the opening was near the fundus of the bladder, and communicated with the peritoneal cavity. The urine escaped from the pelvis through the small cicatricial orifice at the apex of the vagina representing the former uterine site.

Operation, October 15. Present and assisting, Drs. Boyle, Hall, Cassett, and W. F. Taylor. The patient was put upon her back, anesthetized, and her legs flexed as for perineal operation. Jones' self-retaining speculum was inserted, affording an excellent view of the anterior wall and vault of the vagina. The cicatricial ring was dilated, and the fistulous portion of the bladder brought into view. The peritoneal and mucous layers of the wall of the bladder were now separated around

the whole circumference of the fistula. It was found difficult to make the dissection at the angles of the opening, so the external fistulous orifice was enlarged by making a slit in the superficial layer by means of the scissors which were used for the dissection. The upper and lower flaps were now seized with fixation forceps and drawn away from the cystic layer. The dissection was carried to the depth of half an inch. A continuous catgut suture was now passed through the cystic layer in such a way that when drawn up the denuded surfaces above and below the external fistulous orifice would be approximated. Interrupted wire sutures were now employed to close the external flaps, ten being employed for the purpose. In this way the "slit-flap," and all the breadth of the raw surface of which it is capable, were secured; and union was complete in ten days.

The operation differs from Mr. Tait's: (1) In the lateral slits in the external layer; (2) in the greater depth of the dissection; (3) in the employment of the continuous catgut for the cystic layer; (4) in the use of the interrupted wire suture instead of the "tobacco-pouch-draw-string suture," for finally closing the opening.

MEDICAL PROGRESS.

BRONCHO-PNEUMONIA IN CHILDREN.—TORDENS says that the age of the patient is an important matter in prognosis. The younger the child, the less easily does it bear an attack of broncho-pneumonia, and children of less than three months almost always succumb. The malady is much more fatal when consecutive to an infectious disease. The various medicaments recommended are the antiphlogistics, revulsants, expectorants, emetics, excitants, and hydropathy. Hænoch prescribes local blood-letting in vigorous subjects. In case of excessive dyspnoea in strong children, an amelioration may be brought about by subtracting a certain amount of blood. Cadet de Gassicourt denies to blood-letting the power of alleviating dyspnoea, and Tordens holds the same opinion. Dry cupping on the chest may aid in alleviating the pulmonary congestion without impairing the physical powers of the patients. Where there is a tendency to hepatization, indicated by soufflé at the same point for several days, a blister applied after the fever has diminished gives excellent results. Large vesications should not be used. Emetics are indicated when there is abundant mucus secretion from the bronchi; but care should be taken in employing them, on account of their tendency to cause prostration. Ipecac is one of the best emetics to use in broncho-pneumonia of children. In large doses it causes vomiting and lowers temperature. It is also an excellent expectorant. But in cases of capillary bronchitis

or broncho-pneumonia Tordens prefers apomorphine given in doses of 1 or 2 centig. a day. It sometimes causes vomiting, but this is not followed by dangerous prostration. Hydropathy has remarkable efficacy in broncho-pneumonia of children. It causes deep inspirations, produces a cutaneous derivation, and acts favorably by the vapor of water with which it fills the atmosphere. Tordens envelops the patient from the neck to the umbilicus in cold or tepid water compresses. Vapor of water should be constantly disengaged in the room.—*Revue Générale de Clinique et de Thérapeutique*, No. 43, 1888.

CANCER BY SKIN GRAFTS.—The *Centralbl. f. Chirurgie*, 1888, p. 726, mentions the following case, in which carcinomatous nodules were transplanted from one breast to the other by means of skin, and which possesses considerable interest both pathologically and therapeutically. Having determined that a case in which the breast had been previously removed for cancer was too far advanced to permit of a second operation, HAHN obtained the patient's leave to ascertain if it was possible to inoculate the skin over the second breast by pieces derived from the affected skin over the first. Numerous small cancerous nodules were, on April 9, cut off as evenly as possible with grafting scissors, and transplanted by Reverdin's method on the sound breast, after skin on the selected spot had been removed so as to leave an ulcer for their reception. On May 1, the transplanted pieces had taken firm root, and the ulcer was completely covered with epidermis. On May 19, at the edge of the pieces of skin some small projecting nodules appeared about the size of a millet seed; they gradually increased in dimensions, and by June 26 had reached the size of a cherry-stone. Four days later the patient died. On microscopic examination of sections of the transplanted skin, all of which gave a characteristic appearance, it was evident that the main mass of the tumors consisted of a well-developed connective tissue stroma, containing irregular masses of epithelial cells inclosed in it. These masses had clearly insinuated themselves into the healthy tissues, which were on all sides beginning to be invaded by the epithelial nests. The above related facts seem to prove clearly that carcinoma can, under suitable conditions, be inoculated upon healthy tissues; and the practical deduction to be drawn from this circumstance is, that great care should be exercised during an operation to avoid taking up pieces of cancerous tissue in the forceps, and leaving them adherent to the edges of the wound, where they may afterward find a permanent resting place.—*Practitioner*, November, 1888.

fluence of hyoscine, arrives at the following conclusions: 1. The "hyoscinum muriaticum" may be successfully used as a sedative in greatly-excited or maniacal patients. 2. As the effect of hyoscine manifests itself even after a dose of half a milligramme, larger doses should be avoided, though the dose may be increased to one milligramme without any harm. 3. No bad after-effect is observed in such doses. 4. The drug also proves efficient as a hypnotic; but, owing to its depressing influence on the organism, it should only be used in those cases in which other drugs are ineffectual. 5. In five cases—namely, of chronic mania, chronic dementia, and acute insanity—the drug did no good. This was perhaps due to idiosyncrasy on the part of the patients.—*British Medical Journal*, Oct. 20, 1888.

TREATMENT OF CORNS ON THE SOLES OF THE FEET.—This affection is best treated, according to UNNA, by painting a circle of zinc-clay paste about the corn, and, when this has dried on, placing inside the ring a piece of salicyl-creasote plaster muslin (salicyl 40, creasote 40); then the whole is covered over with the paste and allowed to dry. With sweating feet or where the feet are very hot, the part is to be enveloped before the dressing is dry with a soft muslin bandage; this is to be stuck fast with the paste. The dressing should be changed once or twice a week, each time removing the loosened horny layer.

TREATMENT OF INFANTILE ECZEMA.—In the obstinate cases of eczema that occur in children during the second half of the first year, and affect particularly the face and extensor aspects of the extremities, Boeck recommends compresses of a weak solution of nitrate of silver (1 to 500), alternating with an ointment. The compresses are applied covered with gutta-percha paper for two or three hours night and morning, and a soothing ointment during the rest of the day and at night. The unguentum vaselini plumbicum suits very well.—*Vierteljahresschrift für Dermatologie und Syphilis*, June, 1888.

CANNABIN IN BASEDOW'S DISEASE.—VALEIRI, after using cannabin in three cases of exophthalmic goitre, recommends the following formulæ:

R. Cannabin. gr. iv ss
Sugar of milk, q. s.
Make 5 pills.

S.—To be taken in 24 hours.

. Cannabin. gr. iv ss
Distilled water. 5 iij
Syrup of orange flowers. 3 j ℥

S.—Take in teaspoonful doses in 24 hours.

Or, we may prescribe a decoction of 2 or 4:100 parts, or doses of ℥ 15 or 30 of the tincture.—*Wiener Med. Presse*, No. 41, 1888.

EFFECT OF HYOSCINE.—DR. S. FISCHER, of Buda-Pesth, writing in the *Gyógyászat* on the in-

CHICAGO, ILLINOIS.

All members of the Association should send their Annual *Dues* to the *Treasurer*, Richard J. Dunglison, M.D., Lock Box 1274, Philadelphia, Pa.

LONDON OFFICE, 57 AND 59 LUDGATE HILL.

SATURDAY, DECEMBER 8, 1888.

SUDDEN HEART-FAILURE IN DIPHTHERIA.

At the first meeting of the New York Academy of Medicine in November Dr. J. LEWIS SMITH read a most suggestive paper on this subject, admirably supplemental to that read by Dr. Wm. H. Thompson last Spring, on diphtheritic paralysis. In no other disease is sudden heart-failure so frequently met with as in diphtheria, and in no other disease is the physician so likely to be deceived as to diagnosis, since the sudden failure of the heart often occurs in convalescence.

As to the cause of this condition, Dr. Smith thinks that Bouchut and Lagrane's hypothesis, that it is due to endocarditis, is untenable, but that the view that the sudden failure is due to granulo-fatty degeneration of the heart is more plausible. Oertel is in favor of this view, and it must be said that such degenerative changes, occurring in a considerable proportion of the muscular fibres, would render the cardiac contractions feeble, and perhaps inadequate. But in the majority of cases the loss of cardiac power is sudden, and occurs during convalescence, when degenerative changes are not likely to occur. In most cases the cardiac contractile power does not appear to be notably weakened before the attack of heart-failure, as it would probably be if the myocardial degenerative changes were the sole or chief cause. Furthermore, in typical cases of sudden heart-failure the microscope sometimes shows the myocardium to be perfectly healthy. Heart-clot cannot be the primary cause, but is a secondary condition, as shown

by Cadet de Gassicourt and Sanné. Dr. Smith regards the theory of deficient innervation, or a true cardiac paralysis, as the most tenable hypothesis, applicable to the largest number of cases, and the most satisfactory explanation of the cases in which death occurs during convalescence, as well as of those in which the necropsy shows a healthy state of the heart. The theory of arrested or deficient innervation partly explains the concomitant symptoms, such as vomiting, epigastric pain, and dyspnoea or irregular respiration.

Etiologically this cardiac paralysis is associated with and often preceded by other forms of paralysis. What is true of the causes and nature of palatal and multiple paralyses, even of abolition of tendon-reflexes, is most probably true also of cardiac paralysis. We are all familiar with the theories of Gubler and Trousseau, and with the microscopic examinations of Charcot, Buhl, Oertel, and others, which have shown that the peripheral nerves distributed to paralyzed muscles sometimes undergo degenerative changes; and marked anatomical changes have been found in the gray matter of the cord and the roots of the spinal nerves. But the theory as to the etiology of diphtheria that is gaining acceptance, is that systemic infection occurs through ptomaines, produced upon the surface by the microbes, and then enters the system through the lymphatics and blood-vessels. If this hypothesis be true we must attribute anatomical changes in the interior of the body, in the peripheral nerves and cerebro-spinal axis, to the agency of ptomaines, and ptomaines must be the causal agent, acting directly or indirectly, in diphtheritic paralysis. In his recent paper Dr. Wm. H. Thomson writes: "It is quite conceivable that a ptomaine may follow upon the changes which the diphtheritic process sets up in the organism, and thus produce all its characteristic symptoms. The special tendency of diphtheritic inflammation to cause necrotic and gangrenous lesions lends further support to this surmise." The ptomaines spring into existence suddenly and unexpectedly under favorable conditions. Clinical facts appear to harmonize best with the theory that a ptomaine is the direct cause of the paralysis, especially in cases occurring early and quickly cured; although it seems idle to argue that the marked degenerative peripheral and central nerve lesions so frequently present in those who have died with diphtheritic paralysis,

do not prolong and intensify the paralysis, and are in some instances its primary cause.

As to the treatment of cardiac paralysis, Dr. Smith said that it was evident, from the nature of the trouble, that it must be combatted promptly and with the most active remedies. The patient should be kept quiet in bed, with the head low, and alcoholic stimulus administered at once. In sudden seizures hypodermic injections of brandy act most promptly in sustaining the heart's action. Ammonia, camphor, musk and electricity are also of service, as well as the predigested beef preparations, peptonized milk, and other concentrated foods designed for those with feeble digestion. If the urgent symptoms are relieved by these measures, such remedies should be employed as are useful in other forms of diphtheritic paralysis.

DEEPER BRAIN SURGERY.

Will tapping and draining the ventricles of the brain become a definite and legitimate surgical procedure? This question we can answer only by considering a recent paper¹ by that rarely accomplished anatomist and careful surgeon, DR. W. W. KEEN, in which he records a case under the following title: "Exploratory trephining and puncture of the brain almost to the lateral ventricle. For intracranial Pressure supposed to be due to an Abscess in the Temporo-sphenoidal Lobe. Temporary Improvement; Death on the Fifth Day; Autopsy; Meningitis with Effusion into the Ventricles. With a description of a proposed Operation to tap and drain the Ventricles as a definite Surgical Procedure."

The patient was a scrofulous child, æt. 14 years, with a purulent discharge from the ear for six months or more, sudden vomiting evidently cerebral, headache, a tender spot above and in front of the left ear and at no other point, possible aphasia, paralysis of the left sixth nerve, congestion of the optic papilla more marked on the left side, pulse normal, temperature, while not normal or sub-normal, but little elevated until a little while before death. Meningitis and cerebellar abscess were excluded for obvious reasons, as were involvement of the motor region, abscesses in the frontal and occipital lobes, mastoid disease, abscess between the dura and the skull, and plugging of the lateral sinns.

The symptoms pointed to mischief on the left side, and mostly to abscess of the temporo-sphenoidal lobe.

As shown by the title of the paper, the patient died on the fifth day. The autopsy showed that, saving a slight disintegration of the brain tissue in a very thin layer around the track of the drainage tube, the cerebral substance was healthy; and, remarkable enough, no trace could be found of any evidence of puncture in the brain tissue. The internal extremity of the drainage canal, which was one inch long, was within a quarter of an inch of the distended left ventricle. Dr. Keen says, in regard to the use of the needle and grooved director in exploring the brain:

When the dura is intact the syringe must be used, but it should be used with great caution on account of the suction, for, though I had a suction cavity of only seven to ten minims in the barrel of my syringe, yet the brain substance was sucked up into it every time. I cannot but think that the introduction of a grooved director would be safer and certainly, as shown by the post-mortem, did no more injury to the brain substance than the syringe itself, with its certain loss of tissue. The grooved director would allow pus or any other fluid to escape by its deep groove. The sharp point of the needle might readily puncture a vein, a large artery, a sinus, or possibly one of the large nerves, but the blunt end of the director exposes us to no such danger, and invites to a more extended and thorough exploration.

The experience of Beck, Watson and Weir shows that Dr. Keen's objections to the use of the needle are not merely theoretical.

As the result of his observations in this case Dr. Keen proposes tapping of the ventricles as a systematic operation in any similar case of dropsy of the ventricles or of abscess in them. He draws an analogy between the serous membrane of the abdomen and that of the brain, and pleads for a similar treatment in cases of similar disease. As we open the belly and drain in tubercular peritonitis with good success, he proposes the same thing for the brain; and he claims that, on account of the confined position of the brain, the operation is even more urgently necessary, than in the case of pressure in the abdomen. To the possible objection that much drainage of cerebro-spinal

¹ Medical News, Dec. 1, 1888.

fluid would be dangerous, Dr. Keen replies: 1. We do not know that till we try. 2. In his brain-tumor case, in Horsley's spinal-tumor case, and in a case of Championnière's long-continued and abundant drainings were not sources of danger. 3. Experience may show us that possibly in the head, as in the abdomen, simple evacuation of fluid without its continuous drainage, may be not only feasible, but best. Dissections and trials on the cadaver have shown that the motor zone must be avoided, the neighborhood of the fissure of Sylvius must be avoided, and known sense-centres must be avoided; the so-called "latent zones" must be utilized.

Dr. Keen's proposal is certainly a bold one; did it come from a less careful surgeon it might be called rash. But the surgeon of to-day can scarcely think of any reasonable and practicable operation on the brain as some surgeons of Dr. Meigs' day thought of ovariectomy. Dr. Keen proposes three routes as practicable for the operation in question. The limitation of space, however, preclude discussion of them.

EDITORIAL NOTES.

DR. THOMAS G. MORTON, of Philadelphia, has been made an honorary member of the Society of Mental Medicine, of Ghent, Belgium.

GARBAGE CREMATION.—The board of health of San Diego, Cal., does not favor cremation as a method of garbage disposal. Has the board made a proper examination of the matter?

SIR WILLIAM JENNER has resigned from the British Medical Association, it is said, on account of the publication in the *British Medical Journal* of the late Emperor Frederick's note to Dr. Mackenzie.

SCARLET FEVER IN MILWAUKEE.—On Nov. 17 there were 24 cases of scarlet fever in Milwaukee, and within the next week 14 new cases developed. Up to Nov. 24 there had been 12 recoveries and 2 deaths.

COMPULSORY VACCINATION.—Small-pox is causing some alarm on the Pacific Coast and a short time ago fourteen doctors and a number of medical students made a descent on the schools of Portland, Ore., and vaccinated the unsuspecting pupils *vi et armis*. Five hundred and thirty were thus vaccinated in a single day.

FOREIGN BODY IN THE TRACHEA.—Some three months ago a 5-year old boy in Milwaukee put a brass staple into his mouth, and the staple was carried into the trachea in some manner. The boy had periodical attacks of coughing until a few days ago, when during one of the attacks his father held him up by the feet, and the staple passed into the mouth, whence it was removed.

ACTINOMYCOSIS.—At a recent meeting of the St. Louis Medical Society Dr. L. Bremer exhibited the jaw of an ox affected with actinomycosis. Dr. Bremer believes that actinomycosis frequently exists in man, always in the chronic form, and that it is frequently confounded with tuberculosis, bronchial affection, and sometimes with other diseases.

SANITARIUM FOR PHTHISIS.—It is said that a sanitarium for consumptives on a novel plan is to be established at Reineckendorf, a village near Berlin. A large, cylindrical building will be occupied in the upper part by the patients, while the ground floor will be given up to the accommodation of large numbers of milch cows, the exhalations from which will be conducted to the apartments above.

INFANT MORTALITY IN A FOUNDLING ASYLUM.—The Board of Health of Ontario reported on Nov. 13 that 70 per cent. of the infants placed in the Foundlings' Home in Ottawa had died during the year. The establishment known as the "House of Bethlehem" receives a subsidy from the Province. The only charge so far against the proprietor of the institution is that infants do not receive proper nursery and feeding. As yet there is no evidence to show that there has been any criminal negligence, but an investigation will probably be made.

THE COST OF PLEURO-PNEUMONIA AMONG CATTLE.—In an address to the Consolidated Cattle Growers' Convention, which recently met in Chicago, Mr. Salmon said that more than 7,000 head of cattle were destroyed in different States last year in consequence of pleuro-pneumonia. The effect of this announcement was to impress the convention with the danger to be apprehended from the spread of this destructive scourge, and plans have been formulated for representing the matter to Congress, which will be asked to take prompt and effective measures for

the extirpation of the malady and the protection of the cattle interest. It is a matter that concerns not only an important industry, but that involves sanitary considerations of great moment, and should receive prompt attention. Meanwhile, some one should give the cattle growers and other people some idea of the extent to which preventable *human* diseases affects the pockets of the people. The brain of the average man is most easily reached through his pocket-book.

A NEW DISINFECTANT.—It is stated that a new and powerful disinfectant has lately been discovered by a Parisian chemist, and if what he claims for it be true, it will be adopted for very many purposes for which disinfectants are generally used. The basis of the preparation has been obtained from coal-oil, and is a brown liquid of a not disagreeable odor. It is said to be the result of a peculiar saponification of the oil by a chemical process with a mixture of caustic soda. The value of the disinfectant was accidentally discovered by the discoverer, who, desiring to save a pet tree around which a lot of fungous moss had grown, sprinkled some of the mixture around the roots. By repeated use the excrescence was shortly afterward noticed to separate from the tree and fall to the ground. Horses were also sponged with a weak solution of the mixture and it was noticed that flies that generally pester the animals gave them a wide berth.

SOCIETY PROCEEDINGS.

American Academy of Medicine.

Twelfth Annual Meeting, held in the Governor's Rooms of the New York Hospital, November 13, 1888.

TUESDAY, NOVEMBER 13—FIRST DAY.

THE PRESIDENT, DR. FREDERICK HENRY GERISH, of Portland, Me., called the Academy to order at 10:30 A.M. The minutes of the last annual meeting were read and approved. The deaths of the following members were reported: C. R. Agnew, New York; M. H. Borland, Pittsburgh; Howard Pinkney, New York; Theodore T. Wing, Susquehanna, Pa.; E. S. Dunster, Ann Arbor, Mich.; Stephen B. Kieffer, Carlisle, Pa.

The first scientific business was the report of the standing committee on the

REQUIREMENTS FOR PRELIMINARY EDUCATION IN THE MEDICAL COLLEGES OF THE UNITED STATES AND CANADA,

by DR. LEARTUS CONNOR, of Detroit, Mich. In speaking of the preliminary requirements, stress was laid upon the importance of a sound body. In no learned profession is the mortality so great as in the medical. Reference was made to the methods of determining whether or not the colleges fulfil the statements made in their announcements. One of these was by means of decoy letters. This plan last year indicated that the majority of colleges fulfilled these statements. Another method of judging is by examinations of the graduates by disinterested parties, as the army, navy, etc. Positive data are not at present available, but in regard to these examinations the principal deficiency seems to be in the preliminary education. The general verdict of editors is that the average doctor is lamentably deficient even in what is known as common school education. There are in the United States 116 medical schools. According to their announcements 89 exact certain educational requirements, but 19 of these require no more than they can help. It is futile to endeavor to directly influence medical colleges to make these requirements. It can only be obtained by awakening in the mind of the profession and people a sentiment that a definite preliminary education is necessary to the medical student.

DR. A. L. GIBON, U. S. N., offered the following resolution, which was adopted:

Resolved, That the American Academy of Medicine expresses its high approval of the aid afforded to the cause of higher medical education by the College of Physicians and Surgeons of New York, in its recent requirements for matriculation, which it commends to the profession as worthy of adoption.

DR. J. C. WILSON, of Philadelphia, read a paper on

THE CAUSES AND PREVENTION OF THE OPIUM HABIT AND KINDRED AFFECTIONS.

These affections are prevalent to a large extent, though there are no reliable statistics concerning their frequency. The causes may be grouped under three heads: First, example, as shown in the case of those who become opium eaters through the example of friends. Second, suggestion, as is shown in those who fall into these habits through the reading of literature concerning it or from familiarity with the drugs, as in the case of doctors, druggists, nurses and students of medicine. A large proportion of individuals who are led by these causes to contract such habits, do so in the absence of sickness or physical pain. Third, medical prescriptions. It is an unfortunate fact that the greater number of the victims of habitual vicious narcotism become so through the prolonged abuse of narcotics originally prescribed for the relief of pain. Among

the measures suggested for the prevention of the formation of such habits were, first, the dissemination of a wholesome knowledge of the methods by which the opium habit and kindred affections are induced; of the serious character of these affections, and of the dangers attendant upon an ignorant and careless employment of narcotics. Second, a reasonable and temperate presentation of the facts in the popular works upon hygiene. Third, the exercise of every possible precaution on the part of physicians in prescribing narcotics. It is good practice to keep the patient in ignorance of the character of the anodyne used and of the dose. Physicians should personally control, as far as possible, the use of such drugs, and see that they are taken infrequently and in the minimum amounts capable of producing the desired effect; the occasional alternation of anodyne medicaments is desirable. Prescriptions for drugs of this kind should not be renewed by druggists without the written order of the physician. Finally, a merely palliative treatment should not be allowed to assume too great importance in the management of curable painful affections. Under no circumstances, except in the final stages of hopelessly incurable painful affections, should the hypodermic syringe be placed in the hands of the patient. Uniform and efficient laws to regulate the sale of narcotic drugs are desirable. Existing laws relating to this subject are a dead letter; they are neither adequate to control the evil, nor is their enforcement practicable.

DR. R. L. SIBBETT, of Carlisle, Pa., thought the physician should not tell what he is giving when he prescribes opium. He also thought that we should never write a prescription in which the word opium appears.

DR. LEARTUS CONNOR considered it unsafe for the physician to administer a narcotic in his own family. He could give a large number of instances where the wives and other members of physicians' families had become addicted to the use of opium in this way. It is unsafe for the physician to administer opium to himself.

DR. THEOPHILUS PARVIN, of Philadelphia, read a paper on

THE IMPORTANCE OF PRACTICAL OBSTETRICS IN THE COURSE OF INSTRUCTION GIVEN BY MEDICAL SCHOOLS.

A recent visit to Munich, where he spent some time observing the method of teaching obstetrics in the University of Munich pursued by Professor Winckel, made him conscious of the great deficiencies of the American plan of obstetric instruction. The science of obstetrics is admirably taught in our medical schools, by pictures, models, illustrations of various sorts, with preparations of pelves, etc., but the vast majority of American medical students graduate without having witnessed a case of labor. In many medical schools

the diagnosis of pregnancy by auscultation and by palpation is not taught, so that the graduate sees with his own eyes and feels with his own hands. There is also reason to believe that the mortality of private practice is greater than that of hospital practice. Then, too, the unqualified obstetrician contributes largely to the work of the gynecologist. While attendance on poor women at their homes is better than no practice at all, yet the student will derive more benefit from the study of cases collected in a maternity hospital, where many cases can be studied under the instruction of a competent teacher. The practical teaching of obstetrics is to be directly associated with its scientific instruction. There should therefore be a maternity belonging to every medical school in which obstetrics is taught. In large cities there would be no trouble in obtaining sufficient material for this method of teaching. Through the efforts of the author, the Trustees of the Jefferson Medical College authorized the establishment of a maternity department in connection with the hospital. Thirty-four women have been confined without a death. The room being insufficient an outdoor department was established. Here there has been 151 applicants, 106 have been confined, with but one death. This occurred two weeks after labor. The cause of death was not positively ascertained.

Dr. Parvin then described the methods employed at the Munich University, basing his remarks on a report furnished by Dr. J. Clifton Edgar. Obstetrics is there taught by (1) didactic lectures, (2) obstetric clinics, (3) touch courses, (4) operative courses on the phantom, (5) management of labor cases, (6) bedside instruction in the puerperal wards. The student is required to attend obstetrical clinics for nine months. In that time he would at a low average thoroughly examine eighteen gravid or parturient women and to deliver four women.

In concluding Dr. Parvin said: "Why would it not be wise for this Academy, which should be a light and a guide to the American profession, leading it to higher and giving in larger views on those duties and responsibilities, with hearty unanimity declare that practical obstetrics should be made a part of the regular course in every medical college? With the seal of your approval those who are laboring to this end will be given strength and hope."

AFTERNOON SESSION.

DR. F. H. GERRISH delivered the
PRESIDENT'S ADDRESS.

Reference was first made to the necessity for something more than a mere grammar school education as a preparation for the study of medicine. The course of a student without proper preliminary education was traced at length. Until re-

cently any male of the human species, who would pay the necessary fees, found no difficulty in entering. A few years ago several medical schools established a preliminary examination. This was attributed by the speaker largely to the action of the Illinois State Board of Health, to the effect that if the schools wished their diplomas to be recognized in that State, they must have a preliminary examination. He thought that the labors of the Academy should be rather to elevate the standard of medical education rather than the investigation of scientific problems.

The President then referred to certain amendments which had been proposed at previous meetings. One of the Amendments considered, related to Asst. VIII, Sec. I, which now reads: "The Fellows of the Academy in their relations with each other and with their fellow men, agree to be governed by the principles embodied in the present code of ethics of the American Medical Association, and by the constitution and by-laws of the Academy." The amendment suggested "The Fellows of the Academy will be governed by those principles which actuate educated, cultured and honorable men in every profession, and by the constitution and by-laws of the Academy." Dr. Gerrish favored the adoption of the amendment.

Never before had it been appropriate to address the Academy as "Ladies and Gentlemen;" but to-day it was his privilege to use this significant expression. It is not creditable to our country or in keeping with the liberality which therapeutically characterizes our institutions, that a discrimination should so long have been made against women in scientific associations. It is noteworthy that some of the staunchest upholders of a strict preliminary examination as ascertained by the detective work of our committee on the subject last year, were the schools managed by women.

Since the last meeting, the grave had closed over several members of the Academy, and the speaker spoke briefly of the various deceased members.

In order to facilitate the procuring of essays for the annual meetings, it was suggested that a special committee charged with this work be appointed. In reference to the Congress of American Physicians and Surgeons, he thought it advisable for the Academy to consider the expediency of associating itself with the other societies composing the Congress, thus bringing it into more prominent notice than it has hitherto enjoyed.

DR. R. LOWRY SIBBETT, of Carlisle, Pa., read a paper entitled

A FEW WORDS CONCERNING THE ACADEMY.

The Academy was organized in 1876, at a time when the standard of medical education was at its

lowest point. Medical institutions were numerous and their doors thrown open to all, irrespective of qualifications. There were at least also a dozen of so-called diploma mills. It was at this period that the Academy began to explore these novel methods of manufacturing medical practitioners. The addresses by the President and the papers by the Fellows have generally been on some branch of this semi-medical subject and widely distributed among professional and educated classes. These addresses have also pointed out the true and only method by which men may become safe and honorable practitioners. The Academy has strongly insisted upon the necessity of preliminary education. At the time of the organization of the Academy in no State were there laws relating to the practice of medicine that could be enforced. Most of the States now have laws which can be carried out and many have State Boards of Examiners. Graded courses have been adopted in the best medical schools, with preliminary examination and frequent written examinations. The "diploma mills" no longer exist. This is the only Association in which the addresses referred to could have been made, because the sentiments expressed in them have been too much at variance with the sentiments of the majority of the profession.

The Academy is the only society in which an academy qualification is required. There are three departments of activity indicated in the organic law of the Academy, (1) the reading of papers on what may be called the higher science of medicine, (2) the exposure of imperfect methods of medical education, and (3) the bringing into the Academy of eligible members of the profession. The Academy had set a high standard for admission, but he believed that the doors should not be closed against those eminent practitioners who although they did not possess the degree of A. B., had pursued protracted courses of preliminary study in literary schools.

Dr. George Jackson Fisher, of Sing Sing, N.Y., read a paper entitled *The Famous Historic Masters of the Healing Art were Men of Classical Education*.

Dr. L. Duncan Bulkley, of New York, read a paper on *The Relations between the General Practitioner and the Consultant or Specialist*.

WEDNESDAY, NOVEMBER 14,—SECOND DAY.

DR. CHARLES CARROLL LEE, of New York, read a paper on

THE NECESSITY FOR POST-GRADUATION INSTRUCTION IN THE PRESENT STATE OF AMERICAN MEDICAL EDUCATION.

The first Post-Graduate Medical School was opened in New York in 1882. There are now six in operation in different medical centres. These courses are attended by practitioners anxious to

brush up on certain subjects. Some of the colleges strive to provide clinical instruction for medical men but the means at their disposal are not sufficient to provide the instruction required by practitioners. The post-graduate schools are continually increasing in popularity. Here the student in any particular branch is able to devote his entire time to that subject. He is also able to follow the practice of a number of experts, instead of being bound down to the methods of a single medicine. For one mature enough to observe and judge for himself, the benefit of this is obvious. It is difficult to conceive how London, Berlin, or Vienna, can offer greater facilities for clinical teaching than are to-day available in this city. To the medical teacher a frequent European visit is desirable, not only to perfect his methods of instruction but to liberalize his mind, but the time has arrived when if the American teacher of medicine does his whole duty the American student should lack no practical knowledge of his profession.

The consideration of the following

AMENDMENT TO THE CONSTITUTION

was taken up: "The Fellows of the Academy will be governed by those principles which actuate educated and honorable men in *every profession*, and by the constitution and by-laws of the Academy." After a prolonged discussion, the amendment was laid on the table for one year.

The following resolution was presented by the Council and adopted: That the Academy heartily endorses the suggestion of Dr. Parvin, in his Address, that *practical obstetrics* should be made a part of the regular course in every medical college.

DR. HOSMER A. JOHNSON, of Chicago, read a paper on

THE INFLUENCE OF THE WORK OF THE ILLINOIS MEDICAL PRACTICE ACT UPON MEDICAL EDUCATION.

The Illinois State Board of Health was created in 1877. One of its first acts was the passage of a resolution that the diploma of a college graduating two classes in one year would not be considered in good standing after July 1, 1878. This compelled some of the prolific schools to adopt a single graduating term. In 1880 the Board made a study of requirements of medical schools. In 1884 the Board adopted a schedule of the minimum requirements for graduation in the State of Illinois. This has led to an increase in qualifications required by many of the schools. There are now 114 colleges which require evidence of preliminary study as a condition of admission. In 1883 there were only 45. Forty-three colleges now exact a three years' course, as compared with 22 in 1883. The Board has now adopted a resolution defining the phrase "medical colleges in good standing" to mean "only those colleges

which shall, after the session of 1890-91, require four years of professional study, including any time spent with a preceptor, and three regular courses of lectures, as conditions of graduation, and shall otherwise conform to the schedule of minimum requirements heretofore adopted by the Board.

The Treatment of Uterine Disease by other than Surgical Means, by Dr. W. F. Waugh, of Philadelphia, was read by title, as was *The Evils of a Medical Dialect separated widely from Classical English*, by Dr. Edmund Andrews, of Chicago.

The following were elected

HONORARY MEMBERS.

Dr. J. H. Rauch, Springfield, Ill.; Sir Joseph Lister, London; Sir Spencer Wells, London; J. Lucas-Championnière, Paris; Dr. H. D. Didama, Syracuse.

The following were elected

OFFICERS FOR THE ENSUING YEAR.

President—Dr. Leartus Connor, Detroit.

Vice-Presidents—Drs. Peter D. Keyser, Philadelphia; L. Duncan Bulkley, New York; Theophilus Parvin, Philadelphia; George J. Fisher, Sing Sing, N. Y.

Secretary and Treasurer—Dr. Richard J. Dunglison, Philadelphia.

Assistant Secretary—Dr. Charles McIntire, Jr., Easton, Pa.

Place of Next Meeting—Chicago, Ill.

ASSOCIATION ITEMS.

Committee on Dietetics.

CIRCULAR NO. 1.

The Committee on Dietetics appointed by the American Medical Association will hold its next session at Newport, R. I., during the meeting of the Association.

It is thought that the greatest good would result by directing discussion to a single class of dietetic subjects; the committee, therefore have agreed that the papers to be restricted to the consideration of the topics relating to "The Collection, Preparation and Serving of Food for the Family;" and that the Report of the Committee for 1889 shall be limited to the presentation of that class of subjects."

As one topic, among others, belonging to this class, and as one of vital importance to our Nation, it is respectfully suggested that special attention be given to the consideration of the best kinds of food, methods of preparation, and modes of feeding, especially for infants and young persons, to improve the American race.

Papers that may treat of other dietetic subjects

may be read, but will not be incorporated in the annual Report.

The sessions of the committee will be public and open to all who may wish to participate; and any member of the Association may offer a paper for consideration, or take part in the discussions. This new departure, it is hoped, will appeal strongly to those, who, by study and observation, have earned the right to be heard on the subject of dietetics.

While the discussions will be open and free, it is respectfully suggested to all who intend to participate, that the papers should be brief and practical, so as to afford time for their discussion. Each paper should be confined to some specific topic bearing upon the class of subjects under consideration by the committee. What is wanted is not so much variety of themes as fulness and clearness on special topics, in order that precise deductions may be established which shall possess permanent value, and which may in some measure serve as a plain and reliable guide for the busy practitioner.

Papers by eminent men are already announced, and others are promised. The titles of all papers to be read, with the names of the respective authors, will be given through the medical journals. E. A. WOOD, M.D., Chairman,

Pittsburgh, Pa.

FRANK WOODBURY, M.D., Sec'y.,

Philadelphia, Pa.

FOREIGN CORRESPONDENCE.

LETTER FROM LONDON.

(FROM OUR OWN CORRESPONDENT.)

Effects of Stramonium—Climate and Mortality in Great Britain—Verdi's Hospital at Villanova—Anisic Acid a Substitute for Salicylate of Soda—Encysted Calculus—Case of Malingering—Buildings of the Cremation Society—Effects of Pepper and Mustard on Digestion.

A surgeon of the Army Medical Department records the case of a man found insensible at a village in Upper Burmah, who on partially waking out of his stupor, showed symptoms of violent insanity. It seems that about a week previously, he had both chewed and smoked some leaves of the stramonium plant, which had caused first a feeling of sickness and nausea, and then stupefied him. Some amelioration was produced by the administration of forty grains of bromide of potassium, but the patient managed to escape from the military hospital before very much could be done with him.

The climate of the British Islands has been the subject of a good deal of railery by the unintelligent foreigner, but certain statistics of European

mortality which have just been compiled are calculated to show in favor of the British Isles. The United Kingdom after all is the healthiest country in Europe. The rate of mortality in the Roman and Venetian State is 4 in 28, in Greece and Turkey 1 in 30, in Switzerland, Austria, Spain and Portugal 1 in 40, in European Russia and Poland 1 in 44, in Germany, Denmark and Sweden 1 in 45, and in Norway 48. In England the rate of mortality is only 1 in 58, in Ireland it is 1 in 53, and in Scotland 1 in 59.

Interesting accounts have recently appeared of the hospital recently opened at Villanova, and entirely built and supported by Verdi the Composer. Villanova is in close vicinity to the country seat which Verdi has made his home and where he lives in the manner of a farmer, abandoning all music from his thought, and without so much as a piano in his house. The new hospital, an unpretentious but large building, lies in a commanding situation overlooking the Po and with a distant view of the Apennines. There are two wings, one for women, the other for men, and a separate ward is set aside for contagious cases. There is also a hydropathic establishment, and most elaborate arrangements have been made for the disinfection of linen. An efficient staff of nurses and attendants is also provided, and Signora Verdi has made the housekeeping department her special care. The large sums required have been contributed by Verdi, who has also deposited sufficient funds for the maintenance of the hospital. At the opening ceremony only Verdi and his family and the physician were present. No speechifying was allowed, Verdi remarking that the only inauguration necessary was the admission of the sick and ailing, twelve of whom were received then and there.

Anisic acid is talked of as a substitute for salicylate of soda, in the treatment of rheumatism, neuralgia, etc., and as an antiseptic for the preservation of animal and vegetable substances. This product has long been known to cultivators of organic chemistry, it was originally obtained by oxidizing the essential oil of anise, by means of nitric acid, but more recently it has been obtained from some derivatives of the coal tar products. This new product is about to be introduced into therapeutics. It is supposed that it can be given in the same doses as salicylic acid or salicylate of soda, to which the anisate of soda corresponds. At present, however, very little is known with regard to its capabilities as a medicament, but some clinical observations are being made in cases in which the compounds of anisic acid have been administered. It is hoped that they will be found as effective as salicylate of soda without its after effects, or head and cardiac symptoms.

The most interesting case of encysted stone has recently been under the hands of Mr. E. H. Fenwick. The calculus could be felt bi-manually,

and was diagnosed to be hour-glass in shape. The smaller piece was found projecting into the bladder at the level of the left urethral orifice, weighed one ounce and a half, and the larger portion lying in a diverticulum outside the back and base of the bladder; this portion was four ounces and a half in weight, and the size and shape of a large hen's egg. The two portions were connected by a very slender neck. The vesical piece was easily broken off, leaving the neck protruding from the small opening of the diverticulum. The position of the opening rendered much dilatation of it dangerous. It was therefore impossible to extract entire the encystic portion. Attempts to crush it by means of lithotrite or forceps failed. A chisel was then guided through the orifice of the diverticulum and laid upon the stone, elastic counter-pressure was afforded by Petersen's rectal balloon. The stone was then cut through by repeated blows with a mallet. After much careful manipulation, the stone was chiselled into sufficiently small fragments to allow of their being extracted through the orifice. The wound rapidly healed, and in six weeks the patient left Mr. Fenwick perfectly cured.

In the report of the medical officer of Wormwood Scrubs Prison, just published, is given a remarkable case of malingering. A prisoner had, prior to his imprisonment, been for some years considered as quite disabled by a spinal injury, which was an actual fact at first, consequent upon a severe accident. When he was received at Wormwood Scrubs there were features in his case which led the doctor to doubt the genuineness of his then present symptoms, and it was thought that he had recovered from the effects of his original injury to a far greater extent than he was willing to allow. He was, therefore, treated in such a manner as to impress upon his mind the fact that considerable doubt existed as to his real disability to move from his bed. Ultimately finding that few hospital luxuries were given him, after lying in bed as a hopeless paralytic for more than ten weeks in the infirmary, he presented himself at his cell door one morning, having made his bed and put his cell in order. He asked to immediately be let out of the infirmary, and to be allowed to "work like a man," throwing away at the same time with scorn, the surgical support which he had worn day and night for so long a time.

The building of the new chapel, waiting-rooms and lodge in the grounds of the Cremation Society, at Woking, is approaching completion. Fifty-one bodies have already been cremated. The erection of a crematory at Leicester for the Midland Counties is to be considered at a public meeting, and in Glasgow the Scottish Burial Reform and Cremation Society, formed last August, are arranging for the immediate erection of build-

ings, including a chapel and columbarium, on a picturesque site adjoining the cathedral.

The annual course of the Brown Institution lectures will be delivered by Mr. Victor Horsley, at the University of London, on the subject of "Epilepsy."

From some recent experiments it appears that digestion is retarded from about half to two and a half per cent. by pepper, whilst mustard has either no action whatever upon the gastric functions, or but very slightly accelerates them.

SOME PARIS CLINICS.

(FROM OUR SPECIAL CORRESPONDENT.)

Apostoli's Clinic—Vernueil's Clinic—Charcot's Clinic—Therapeutic Notes.

Dr. Apostoli has a clinic for diseases of women, with special reference to the treatment of such conditions with electricity, on Monday, Thursday and Saturday, at half-past two, Rue du Jour, No. 19. I consider this to be, in many particulars, the best gynecological clinic in Europe, either: 1st. For those who wish to examine a great variety of rare as well as of ordinary cases; 2d. For those who wish to study intelligently and honestly recent methods in conservatism.

Those who have raised objections to his method have done so, 1st, from theoretic reasoning; 2d, from a want of success, due probably to a want of exactness in following out necessary directions. A man is apt to believe the evidence of his own eyes, and the testimony of a multitude of reliable witnesses can be disputed only upon the ground of defective eye-sight, defective diagnosis, defective balancing of *post hoc* and *propter hoc*, or of illogical deductions of enthusiasm. Even the most bitter agnostic, be he honest and well-balanced, would hardly ascribe this congregation of psychoses to a group, however justly they might apply to an individual. Theoretical fancies, in the face of clinical facts to which they oppose themselves, can carry no force. Such theories have concerned themselves chiefly with *immediate* electro-chemical action, forgetting the *continued* intra-polar molecular action, which is the important factor of all electrization.

This is what the gynecologist aims at in the galvanic treatment, and galvano-caustic treatment of myoma. He does not expect as much from the immediate puncture as he does from the effect upon the molecules between the poles—the inter-polar zone—which effect is progressive. The advance of a great science cannot be arrested by a doubtful smile. If it be of value, it will pass onward and upward, even if it should do so over a multitude of dead opinions and languishing individualisms.

Ovarian pain, generally hysterical, pain con-

fined to the ovary and not experienced elsewhere. This is treated with the bi-polar Faradic current, generated from a *fine* wire battery, which gives a higher tension. The rubber cone, about as large as a Simpson's uterine sound, tipped at the point with platinum, holds both the positive and negative poles, to which the currents are carried through a square base. Such cases as these always profit immediately by the application. It soothes the pain at once. The question I raised with Dr. Apostoli was, whether such an isolated pain might not be the evidence of a generally unstable psychic condition which could be met more intelligently by constitutional treatment; whether such pain, though felt in the ovary, might not be due to a disturbance of the higher centres—a misinterpreted pain, so to speak—since absolute pain of an organ could only really exist with actual disease. That Faradism for a reflected neurosis could not be permanent, unless the condition *reflecting* it, could also be reached and benefited. However, apart from such metaphysical reasoning, uterine bi-polar Faradism *always* arrests the pain.

Hæmorrhage from Tumors.—Apostoli has not failed in a single instance, during my term of observation, in perfectly arresting these blood-losses after one, two, three or more sittings. I have seen him carry the current to 150 or 200 milliamperes, the positive *carbon* point in the uterus, the negative attached to a belly-pad of potter's clay. I have not seen a woman complain of anything more than a slight uneasiness, though a current of 200 milliamperes was used. A sitting lasts ten or fifteen minutes, and the carbon electrode is withdrawn from the fundus toward the cervix, so as to include, as far as possible, the whole interior surface of the uterus. There are certain cases where the negative pole is used within the uterus, in order to get primarily a *destructive*, and secondarily a *ciatricial* effect. If it shall be demonstrated beyond all question of reasonable doubt that the clinical symptomatology of myoma ceases to become prominent after the application of galvanism, without endangering life, we have reached a plane of scientific progress higher than that occupied by the laparotomist; and I can conceive of no necessity for the dangerous operation, if there be no discomfort from the tumor.

Salpingitis.—I have seen three cases of catarrhal (?) salpingitis, and two of gonorrhœal salpingitis, very happily treated with galvanopuncture. One case I saw who bore a child after being treated by Apostoli for a number of months for a salpingitis.

Other Conditions.—A woman came into the clinic the other day, with a tremendous peri- and parametritis filling up the fornices, and due to a specific salpingitis. In acute perimetritis Apostoli does not hesitate to use Faradism in the uterus, but he does it with the greatest care possible.

In this case, owing to the purulent discharge, he used the galvanic current, + pole in the uterus, and a current of 100 milliamperes, which the patient bore well. Later he uses galvanopuncture. The case is a grave one. The bugbears of gynecology, chronic para- and perimetritis, are admirably conquered by from 50 to 150 milliamperes of galvanism. I saw Engelmann over and over again relieve such cases in Berlin.

Verneuil's Clinic.—A man came into La Pitié whose index finger had been torn off by a machine just above the first phalanx. The whole hand was kept constantly immersed in a large basin of 2 per cent. carbolized water. Nothing more. Professor Verneuil said, that during his practice of over forty years, he had only amputated a finger in perhaps four instances. Because he considered it exceedingly bad practice. These cases all did well when treated by the antiseptic bath; and that it was not good surgery to amputate in these cases of suppuration. He also demonstrated a man, whose prostate he had *scraped* for tuberculous disease, and who was doing well. Another most instructive case, was one in which a man was unable to swallow by reason of œsophageal constriction, but who was fed through the nares, by means of a very ingenious tube. This same arrangement he proposes trying on a man whose tongue he will extirpate for cancer in a few days. Operate early, operate largely, take out all suspected material and feed intelligently, are the points upon which he insisted, as he lectured upon cancerous disease of the tongue. Professor Verneuil offers the following conclusions as to the transmission among men of tetanus:

1. Human communicability is not substantiated by a sufficient number of cases.
2. If transmission does not seem to depend upon the atmosphere, but upon contact, direct or indirect.
3. We have no decided case of record to bear out the theory of immediate contagion, many clinical observations attest the truth of the second, or indirect form.
4. It is very difficult to trace the route through which the contagion has been carried from the first case to others.
5. It behoves us to study with patience this question so pregnant with importance.

Charcot's Clinic.—Professor Charcot has a clinic at nine o'clock, Tuesday and Saturday at La Salpêtrière. On Tuesday he lectures upon a given case, and upon Saturday the wards are visited. Whatever opinion we may have as to the permanent value of Charcot's work two facts are indisputable: 1. The large intelligence and thorough mental equipment of the man. 2. The number of rare cases. These cases are rarely seen outside of La Salpêtrière, for some reason unknown, and which Charcot himself, only a day or two ago,

said was to him an enigma. But apart from the hystero-epileptics, there came here cases of the largest possible interest to the neurologist. I have listened to two conferences, one on *homonymous hennopia and crosses amblyopia*, and the other in *left-sided sciatica*, and I was greatly struck both by the originality displayed by the Professor in illustrating the cases, by his acuteness of diagnosis, and by the large scope of his research. Incidentally, he alluded to the operation of oöphorectomy for the alleviation of hysterical symptoms, and I was glad to find myself sustained in the point I raised at the 9th International Congress, that such operative procedures were irrational, based neither upon sound physiology or pathology, by a man of such eminence. What neurologist is great enough to diagnose peripheral ovarium hysteria, with derangement of the brain, when neither before the operation, nor after the entirpation of the ovary, nor perhaps after death from the operation, can the microscope discover any pathological lesion? What is the primary lesion? Is it not much more natural to suppose that the mischief is in a higher ganglia, and that the ovary suffers only as a reflex periphery.

Therapeutic Notes.—M. Constantin Paul is using saccharin in solutions of 1:250 and 1:500 as an antiseptic dressing in diseases of the eye. Dr. Rovighi, of Bologna, is advocating the use of *strophanthus* as an antipyretic. In four cases of consumption he reduced the temperature 2° to 3° . Dr. M. R. Cholewa treats coryza with an oily solution of menthol, 20 parts to 100. M. Henocque denies the activity of antipyrin and of acetanilide in the reduction of oxyhemoglobin. He is now experimenting with phenacetin. H. R. B.

DOMESTIC CORRESPONDENCE.

LETTER FROM NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Sudden Heart-Failure in Diphtheria.

Dr. J. Lewis Smith read at the first meeting of the Academy of Medicine in November, an admirable paper on "Sudden Heart-Failure in Diphtheria." Towards the close of his paper he examined by the light of clinical experience the prevailing theory that diphtheritic paralysis results from anatomical changes, peripheral or central, or both, in the nervous system, and to inquire whether it was adequate to explain the paralysis as it ordinarily occurs—whether cardiac paralysis or the other forms. The following he gave as some of the objections to it:

1. Cases occur in which carefully conducted microscopic examinations reveal an apparently normal state of the nerves supplying the paralyzed part and of that part of the cerebro-spinal axis from which the nerves arise.

2. Palatal paralysis sometimes occurs as early as the second or third day of diphtheria, and loss of the tendon reflexes as early as the first day; and it seems improbable that a peripheral neuritis or anatomical changes in the cerebro-spinal axis such as to cause paralysis should occur at so early a date.

3. In its commencement diphtheritic paralysis often exhibits what Trousseau designates as mutability; suddenly shifting from one group of muscles to another. It would seem impossible that there should be a sudden recovery from the paralysis, and then perhaps on the following day a recurrence of it, if it resulted from degenerative nerve changes, either central or peripheric. A persistent cause should produce a continuous effect.

4. Microscopists who have discovered degenerative changes in the peripheral nerves supplying paralyzed muscles, state that while some of the nerve-fibres have undergone complete or nearly complete degeneration, others have been affected with only partial degeneration, and still others seem to be intact; a condition which would hardly account for the complete paralysis often met with, as, for instance, in the velum palati.

5. Diphtheritic paralysis, both motor and sensory, is frequently limited to the parts supplied by a single branch of a nerve, while all the other branches preserve their normal function. This fact, while not antagonistic to the theory that peripheral nerve lesions cause the paralysis, affords a strong, if not conclusive, argument against the theory that central nerve lesions are the cause.

In the discussion on the paper Dr. A. L. Loomis said that he had been accustomed to regard diphtheritic paralysis and heart-failure as not always dependent on the same cause. In the early stages of diphtheria it had seemed to him that heart-failure was due to the direct action of the poison, whatever that might be, as was no doubt the case in other diseases, especially typhus fever, in which sudden death not infrequently occurred from this cause. When the accident occurred in the advanced stages of diphtheria he had considered that it was caused by peripheral neuritis, although he did not deny that there was possibly not a sufficient basis for such an assumption.

Dr. Beverley Robinson said that he was still of the opinion that cardiac failure in acute cases, in the majority of instances, was connected with the ante-mortem formation of clots in the heart, especially the right heart. When a hospital interne in Paris, he had made a large number of autopsies in such cases, and he had never found any lesions of the peripheric nerves. In his experience death did not always occur rapidly; the symptoms of heart-failure often continuing for a considerable time before the fatal termination. After death there would almost invariably be found fibrinous clots, and from their character he

believed that they were formed ante-mortem, and were to a greater or less extent the cause of death.

Dr. A. Caillé spoke of the importance of keeping all patients suffering from diphtheria, strictly confined to bed, and of giving them sufficient stimulus, for the purpose of counteracting, as far as possible, the tendency to heart-failure. He also mentioned one case in which fatal heart-failure was apparently brought about by an error in diet.

Dr. Seibert expressed the opinion that heart-failure occurring in the early stages of diphtheria was due to the direct action of the poison of the disease upon the central nervous system, and that when it developed later on it was due to pathological changes in the cardiac muscles. In all the cases that he had known of, the attack was brought on by the attempt of the patient to make some exertion.

Dr. A. Jacobi said that it was probable that some of the sudden deaths in diphtheria were due to syncope, the result of anæmia of the brain brought about by exertion, as was sometimes the case in pneumonia. There was one peculiar condition that might be mistaken for heart-failure in the later stages of diphtheria, viz.: paralysis of the muscles of respiration. It usually followed the other forms of paralysis, and was characterized by shallow respiration, with a good deal of resulting dyspnoea and rapidity of the heart's action. In such cases electricity in short sittings, and strychnia by hypodermic injection, are the most efficient means of treatment. Being aware of the tendency to fatal heart-failure in diphtheria, it was the duty of the physician in every case of the disease to do all in his power to guard against such an accident. The indications are to save the strength of the patient by feeding and tonics, and especially to fortify the heart by means of alcohol and such agents as digitalis, spartaine and strophanthus. In every case of diphtheria we had to deal with sepsis, and alcohol was therefore of the highest possible value. He believed that no patient with this disease could be injured by alcohol, and that even the most courageous physicians often erred in not giving enough of it. If the choice were offered him between alcohol and all other remedies in diphtheria, Dr. Jacobi said he would unhesitatingly select the former as affording the best chance to the patient. In brief, then, the indications for the prevention of heart-failure are to save the strength, combat sepsis, and sustain the heart.

In closing the discussion Dr. Smith said that, since the stomach and lungs, as well as the heart, were implicated, the inference was that the cause of the trouble was some affection of the nerve supplying the three organs, the pneumogastric. It was a fact that a certain proportion of those attacked with heart-failure recovered, and that in some of those who died there was for a time an

amelioration of the symptoms; and it seemed to him that this would not be possible if the trouble were due to heart-clot, which would undoubtedly be a permanent condition, unaffected by any treatment that might be adopted. It was also a fact that paralysis of some form almost invariably preceded the heart-failure, and this would seem to indicate that the latter was due to the same cause as the paralysis.

P. B. P.

Spontaneous Paracentesis Abdominis at Umbilicus, in Anæmic Ascites.

WITH LARGE MULTINODULAR FIBROID TUMOR OF UTERUS.

Dear Sir:—Never having met with a recorded case of the above complication, I present a report of the same, owing to its extraordinary rarity. Several years since, I attended Mrs. — for metrorrhagia, coincident with the development a large fibroid tumor of the uterus. Her general condition consequently was not good, yet she could exercise and had a fair appetite. Later, her circulation became impoverished, resulting in general anæmia, some anasarca, with ascitic accumulation, ultimating in an immense circumference or rotundity. This condition has existed for several months. She looks cadaverous, yet has a voracious appetite. Dyspnoea and the usual concomitant of such a state of health, are present, not to an intolerable extent however. On August 5, I was summoned to attend her. I examined the abdomen. I found the umbilicus protuberant, of six inches in diameter, similar to *hernia umbilicalis* (yet there was no hernia), only the dropsical infiltration, which had found an outlet through the parietes of the umbilicus, sufficiently large to admit the exit of a drop of the fluid which continued to drop, guttatim. Nothing was to be done, hence I advised non-interference. Drainage would continue to the level of the orifice, and possibly closure would be effected, yet the enfeebled structure would give away under the heavy recurrent pressure. Considering the adhesions existing between the tumor and the peritoneum, and the self-evident malignancy of the same, extirpation could not be entertained; hence, she will be compelled to endure the same until death comes to her relief.

GEO. N. MONETTE, M.D.

17 Prytania St., New Orleans.

"What is the Matter with the Candle Test of the Visual Field?"

Dear Sir:—It seems hardly right to be making a fuss over anything so presumably well-known and generally used as the candle test of the visual field. But Dr. Cheatham's pertinent query (JOURNAL, November 17) in connection

with Dr. Chisolms' report can, I regret to say, be applied to other cataract operations—as in the following instance :

In some years past I have had under observation a patient (senile) who had chorio-retinitis in the left eye and steady maturing cataract in the right. Recently the cataract became fully matured and the question arose as to an operation. The chorio-retinitis in the left eye had been for some time at a standstill and there was fair eccentric vision sufficient for getting about, self-help at the table, etc., but not for reading or writing with any satisfaction. My patient was naturally not content in this condition and hoped for relief (at least to the extent of reading coarse print) through a successful extraction of the cataract in the other eye. I therefore made a careful examination by the candle test and finding that the light was *not* quickly perceived and located (particularly at the center of the field) I was compelled to give it as my opinion that a successful extraction would not restore the reading power or much improve vision generally.

Later on my patient visited a neighboring city, was there given a more favorable prognosis, and submitted to the operation. The operation was neatly done and the healing normal. The patient returned home some weeks later, but after the lapse of several months the power to read had not returned, nor is it now expected. In the region of the macula, easily discernible with the ophthalmoscope through the unobstructed pupil is a large white patch (atrophy) similar to the one in the left eye, and whose presence I from the first suspected, through the failure to stand the candle test.

Dr. Cheatham's communication seems not to have been ill-timed. Respectfully yours,

H. B. YOUNG, M.D.

304 N. 3d St., Burlington, Ia., Nov. 19, 1888.

BOOK REVIEWS.

Second Annual Report of the STATE BOARD OF HEALTH AND VITAL STATISTICS OF PENNSYLVANIA, Transmitted to the Governor, Dec. 1, 1886. 8vo., pp. vi, 1056. Harrisburg: Erwin K. Meyers, State Printer. 1887.

As may be seen from the dates in the above title, the *accouchement* of the bodies politic that gave birth to this volume was perhaps painful and certainly protracted. The report embraces the operations of the Board for one year, and it has taken almost two years to get it from the Secretary, through the Governor, Legislature, and State Printer, to our desk. A note to the title page explains that "legislative permission for the printing of this report was not accorded until near

the close of the session of 1887. Thus it has required about a year to get the volume through the State Printing Circumlocution Office. May we not hope that the report for the year 1888 will be ready for exhibition at the time of the fourth centennial of the discovery of America—1892?

Part I of the volume (44 pages) contains the minutes of the Board. Part II is in the form of appendices, reports of standing committees, on Sanitary Condition of Cities and Towns, on Epidemics and Special Sources of Disease, of Inspections, of Quarantine and Disinfection, Proceedings and Papers of the State Sanitary Convention, Geographical Distribution of Consumption of Lungs and Malarial Diseases, by Dr. William Pepper, Legal Opinions and Legal Proceedings, Compendium of Laws relating to Public Health and Safety of Pennsylvania, and Decisions relating thereto, Sanitary Conferences, etc. This is scarcely more than a meagre synopsis of the table of contents.

As may be found in almost any report of this kind, there are plenty of texts for homilies on the penny wisdom pound foolishness of legislative bodies. The report of the Committee on Registration and Vital Statistics shows that the legislature failed to make reports on vital statistics compulsory, and that no provision was made for meeting the expenses of reporting to the Board. The report of the Committee on Water-supply and Drainage, Mr. Rudolph Hering, Chairman, is very full. The report on Public Institutions and School Hygiene contains a very suggestive and practical paper on alms house construction, by Dr. R. Lowry Sibbett, of Carlisle. Legislative weakness is again shown in the report of the Committee on Adulterations, Poisons, etc., the funds supplied the Board being insufficient to permit of any amount of work being done in regard to these matters.

The reports on the sanitary condition of cities and towns cover Towanda, Altoona, Bethlehem, drowned lands in Luzerne Co., Allentown, Bristol, Blairsville, and Johnstown. We are glad to see that Dr. Germer calls attention to the polluted drinking water on board passenger cars. There is absolutely no excuse for this, and we hope that some of our legislative bodies will come to their senses long enough to correct this evil.

The reports on Epidemics and Special Sources of Disease include reports on a fatal outbreak of trichiniasis at Bethlehem, and several outbreaks of smallpox and typhoid fever. The reports on Inspections cover a large number of places. Under reports on Quarantine and Disinfection is a report on Japanese rags; and one on the quarantine of smallpox in the Port of Philadelphia, by Dr. Benjamin Lee, Secretary of the Board.

At the sanitary convention held at Philadelphia in May, 1886, thirty-two papers were read, all of which are printed, and we fear buried, in this re-

port. We would call the attention of the Pennsylvania Board to the manner in which proceedings of sanitary conventions in Michigan are printed by the Health Board of that State. For aught we remember to the contrary, the proceedings of this convention may have been published separately; but memory is sometimes a little clouded in regard to historical events. These papers, which cover more than 200 pages are too valuable to be buried in a large, not generally accessible report, as is the case with Dr. Pepper's masterly contribution to the "Geographical Distribution of Consumption of the Lungs and Malarial Disease in the State of Pennsylvania." This, however, has been issued in separate reprint.

For reference the "Compendium of the Laws relating to Public Health and Safety of the State of Pennsylvania, together with decisions of the Supreme Court and County Courts relating thereto" is very valuable. Another appendix contains correspondence relative to regulations for the transportation of dead bodies in the different States of the Union.

Taken altogether, this report is a most creditable one. The Pennsylvania Board, like almost every other Board that has no money for purchasing legislative influence, has been hampered by legislative restrictions and inactions. Scarcely had it begun its work before it was called upon to show cause for its establishment. The present volume is an answer to that question, and a complete answer; and we venture the assertion that if the people of the State of Pennsylvania have any cause for complaint, they must find fault with their representatives in the State Legislature. So far as we can see the Board has done its duty to the best of its ability. We hope that the report for 1887 will appear before the last quarter of 1889.

The Physician's Leisure Library. **THE THEORY AND PRACTICE OF THE OPHTHALMOSCOPE.**

By J. HERBERT CLAIBORNE, Jr., M.D. Detroit: Geo. S. Davis. 1888. Chicago: W. T. Keener.

Dr. Claiborne's little book consists of eight chapters; the first three are devoted to the principles of optics as a preface to the better understanding of the scientific use of the ophthalmoscope. The other chapters treat of the construction of the instrument, its use by the direct and indirect methods, the detection of anomalies of refraction, and the normal and pathological state of the eye. Much attention is devoted to the vessel and shadow test. The latter method is generally employed in England, and according to the author's opinion should receive more recognition in our own country. The work is clear concise and practical. It contains a great deal of information. It is formulated in such a manner as to prove a guide and instructor to the student while examining the patient.

MISCELLANEOUS.

TO MEDICAL MICROSCOPISTS.—In behalf of the "American Association for the Study and Cure of Inebriety" the sum of one hundred dollars is offered by Dr. L. D. Mason, Vice-President of the Society, for the best original essay on "The Pathological Lesions of Chronic Alcoholism Capable of Microscopic Demonstration." The essay is to be accompanied by carefully prepared microscopic slides, which are to demonstrate clearly and satisfactorily the pathological conditions which the essay considers. Conclusions resulting from experiments on animals will be admissible. Accurate drawings or micro-photographs of the slides are desired. The essay, microscopic slides, drawings or micro-photographs are to be marked with a private motto or legend and sent to the Chairman of the Committee on or before Oct. 1, 1890. The object of the essay will be to demonstrate: *First*, Are there pathological lesions due to chronic alcoholism? *Secondly*, Are these lesions peculiar or not to chronic alcoholism? The microscopic specimens should be accompanied by an authentic alcoholic history, and other complications, as syphilis, should be excluded. The successful author will be promptly notified of his success, and asked to read and demonstrate his essay personally or by proxy, at a regular or special meeting of the Medical Microscopical Society, of Brooklyn. The essay will then be published in the ensuing number of *The Journal of Inebriety* (T. D. Crothers, Hartford, Conn.) as the prize essay, and then returned to the author for further publication or such use as he may desire. The following gentlemen have consented to act as a Committee: Chairman, W. H. Bates, M.D., F.R.M.S., Lond., Eng., (President Medical Microscopical Society, Brooklyn), 175 Renssen St., Brooklyn, N.Y.; John E. Weeks, M.D., 43 West 18th St., New York; Richmond Lennox, M.D., 164 Montague St., Brooklyn, N. Y.

IMMIGRANT INSANE.—During October, 1888, among the insane taken charge of by Cook County, Ill., were the following: James Dargan, who left Ireland four months before, and was brought to America by his sister, after being discharged from the Irish police force on account of insanity; James Spain, three months from Ireland; Caroline Sauritzen, three months from Germany; Charles Koch, six months from Germany; Hannah O'Sullivan, residence Dublin, Ireland, but a few months in America. All these were, as far as could be ascertained, insane before coming to this country. The total contribution of insane paupers from Europe to Cook County amounts to fifty for this year alone. If the other principal cities of the United States are as generously treated by foreign governments we will be able to close all their asylums and poorhouses in a few years, and by making aldermen and county commissioners of foreign criminals their penitentiaries will be emptied into American political offices.—*America*.

PHYSIOLOGICAL MARRIAGE.—Taking part in the discussion of the "Matrimonial Question," which has become epidemic throughout the British Isles, even to the abatement of Irish grievances, the *British Medical Journal* remarks that "the remedy (for unhappy marriages) seems to us to lie not in weakening the stringency of the bond, but in providing that it shall be entered into with an adequate knowledge of all the conditions attached to it and willingness to submit to them. For this some amount of physiological teaching is indispensable, and there need be no difficulty in imparting it without the slightest danger to innocent minds. We are firmly convinced that, if unions were arranged in accordance with well understood scientific principles more often than they now are, we should hear less of the unhappiness or 'failure' of marriage."

LARD ADULTERATION.—The National Board of Trade has expressed itself pretty strongly on the subject of lard adulteration. It has adopted a preamble and resolutions proposed by the Chicago Board of Trade declaring that "large quantities of a compound made from the fats of various animals and vegetables" are "placed on the home market, shipped abroad, and branded as lard." It also expresses a fear that this practice may enable foreign refiners to induce the Governments of France and Germany to prohibit the importation of all American lard, "thus damaging our export trade and diminishing the consumption of honest lard at home, to the financial detriment of the agricultural interests of this country, which to-day own about 50,000,000 hogs, worth \$300,000,000, and further damaging America's good name in the commerce of the world."

When the statement that a compound made from the fats of "various animals and vegetables" is extensively made in this country, and exported as lard, is put forth with the sanction of the Chicago Board of Trade, it is likely to be believed, and it would not be very surprising if it should precipitate that action on the part of foreign Governments which the Board professes to fear. Foreign refiners can now go to their Governments armed with the preamble and resolutions adopted by the National Board and say: "Here we have an admission by the highest American authority in such matters that the stuff sent over here from America and sold as lard is a vile compound of the fats of we know not what animals—dogs and cats, it may be—and vegetable oils of which we are equally ignorant. Ought you not, therefore, to protect the public health by excluding all packages represented as containing lard coming from America?" Governments which have shown their willingness to seize upon any pretext for the exclusion of American products may not be disposed to resist an appeal so fortified.

The remedy proposed by the Board is the enactment of such laws and regulations by Congress as will compel all dealers and refiners to brand all adulterated lard as "compound lard," or in some way which will clearly distinguish the impure from the pure article. It is undoubtedly the right remedy, but it may come too late. At all events Congress ought to provide it without delay. It might have been better for the Board to adopt a recommendation in regard to adulterations generally and send a committee to Washington to represent to Congress the urgent need of prompt action in regard to lard, without putting forth a statement concerning adulterations which may do much harm before the proposed remedy can be adopted.—*Chicago Herald*.

HEALTH OF THE DISTRICT OF COLUMBIA.—Health Officer Townshend, in his annual report to the Commissioners for the last fiscal year, says the general health of Washington remains unimpaired, and the community has good reason to congratulate itself upon existing conditions. The total number of deaths was 5,040, of which 2,778 were white and 2,262 were colored persons. The mean average death-rate of the total population for thirteen years was 23.88 per 1,000, per annum, while for last year it was 22.40. The death-rate of the white population was 18.52, and for the colored, 30.16 per 1,000, per annum. The population upon which the death-rate is estimated is 225,000 souls, 150,000 white and 75,000 colored. There are 426 nuisances accredited to "ashes." He reiterates his recommendation for the removal of ashes at public expense. He considers the necessity for this paramount. He estimates that it would cost \$25,000 per annum. The Inspector of Plumbing regrets that Congress has not yet authorized the inspection of the plumbing in all houses used as dwellings. "Many of our public buildings are unsafe on account of unsanitary plumbing," says the Inspector, "and only occupied at the imminent risk of health and life."

Attention is called to the necessity for proper appliances for disinfecting bedding, clothing, etc. A general

revaccination is suggested, in order that the unprotected may be protected in the event of small-pox being introduced into our midst. This disease, though reported in twenty-one States in the last six months, has not gained an entrance into the District. Regarding the disposal of the dead, he says: In several of my reports I have called attention to the subject of the disposal of the dead, and I desire to reiterate, in terms as strong as possible, that, in my opinion, the time has well nigh arrived when this subject must be taken into earnest consideration. The days for cemeteries are passing rapidly by, and I believe ere long the few crematories which have been established in the United States will be largely multiplied.

He recommends the appointment of a chemist, an increased clerical force for his office, a larger appropriation for the removal of garbage, the establishment of a city wharf, arching of James Creek Canal, and the granting of marriage licenses put under the Health Office.

A BUREAU OF HEALTH.—Senator Gibson introduced a bill in the Senate, on Dec. 4, for the establishment in the Interior Department of a Bureau of Health, to be under the direction of a Commissioner, who shall receive a salary of \$5,000 per annum. It also provides for the appointment by the President of a Health Commission, to be composed of twenty members, who shall be divided into six sections, as follows: Five for the yellow-fever section and three each for the cholera, typhoid fever, scarlet fever, small-pox, and diphtheria sections. Each member of the commission shall receive an annual salary of \$1,200, and it shall be his duty to investigate the cause, origin, and best mode of prevention of the diseases mentioned. Five members of the commission shall be organized into a quarantine commission, whose duty it shall be to examine into and report upon the efficacy of the quarantines at the various seaports of the United States. Upon the report of the commission to the Health Commissioner that the quarantine service at any port is inefficient the Commissioner is commanded to direct the Collector of Customs at the port to refuse entry to any vessels, goods, or persons coming from any infected place unless the vessel shall have undergone quarantine at some National quarantine station. The Health Commissioner is directed, whenever called on by the Governor of a State, to make rules and regulations and take measures for the suppression of any infectious disease. It is made the duty of Consular officers to make weekly reports to the Health Commissioner in regard to the sanitary condition of foreign ports. It is made unlawful for any person to obstruct commerce between the States or with any foreign country except in accordance with the rules prescribed by the Health Commissioner. An appropriation of \$75,000 is made for the expenses of the bureau annually, and an appropriation of \$500,000 is made to be drawn upon whenever necessary for the suppression of any contagious or infectious diseases.

THE ST CHARLES CO., MO., MEDICAL SOCIETY held one of the most interesting meetings, on November 20, in the history of the organization. Every section of the county was represented. In the afternoon the aged Dr. John A. Talley, of Weaverville, the retiring President of the Society, delivered his annual address. He condemned the theory of permitting nature to take its course in many cases, and said doctors did not disagree as often as popular opinion gave them credit for. Dr. Bruere read a paper on "Measles and its Complications." Dr. H. H. Vinke read a paper on "Cerebral Tumors and Abscesses." Discussions and the presentations of individual cases followed. After adjournment a visit was paid to the County Asylum, and the institution, together with the new insane department, was inspected. The next meeting will be held in St. Charles on the first Tuesday in February.

SANITARY CONDITION OF PENNSYLVANIA COAL MINES.

—A correspondent of the Chicago *Herald* says: One cannot but be struck with the poor condition of these mines, both as to ventilation and roof supports. The first is insufficient, and the last is criminally absent in so many cases that death from a "falling roof" has become alarmingly common. Both ventilation and roof support cost the mine-owners considerable, and, upon the principle that pervades all their mines, expenses are kept at the lowest notch, in order that the profits may reach the highest. As a consequence the mines are little more than half ventilated, and less than half supported by the necessary pillars to prevent the slate roof from falling upon the unfortunate workmen. Hence it is that the miners' hospital here is nearly always crowded, and the Potter's Field is every day extending its borders.

CONVICTION OF AN ILLEGAL PRACTITIONER.—In New York last week Francisca Ritch was sentenced by Recorder Smyth, for the unlawful practice of medicine, to 100 days' imprisonment in the penitentiary and the payment of a fine of \$100. The delinquent has had a large practice among women for many years, and this is her second conviction. Were it not for the pernicious influence of such a sentence, it would be ridiculous, but considering the amount of evil a malpractitioner causes, there can be no excuse for administering such a light sentence. Ten years in the penitentiary should be the lightest punishment for such an offense.—*America*.

NOTICE.—Those parties who answered the advertisement of Dr. E. A. Waggener, Carrollton, Mo., which appeared in THE JOURNAL of Nov. 24, will please repeat their answers to him, as the whole of their letters were destroyed by accident, thus leaving him without their addresses.

A CAUSE OF LUNACY.—Mr. Baron Huddleston's latest *obiter dictum* is not bad. "Such was the intricacy of the lunacy laws," said his lordship, "that they had a tendency to reduce persons who gave an abstruse study to them into persons for whose benefit they were intended."

NEW HOSPITAL AT TACOMA.—Plans for the new hospital are nearly completed, and excavating for the foundation will commence in a few days. The building will be a handsome one, and will cost \$15,000.

Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department U. S. Army, from November 24, 1888, to November 30, 1888.

Major Ely McClellan, Surgeon, having reported to the Division commander, on the 23d inst., as required in par. 15, S. O. 261, c. s., A. G. O., is assigned to duty as attending surgeon at these headquarters, and as examiner of recruits at Chicago, Ill., from that date. Hdqrs. Div. of the Missouri, Chicago, Ill., November 24, 1888.

Major Henry M. Cronkhite, Surgeon, is granted leave of absence for two months, by direction of the Secretary of War, to take effect upon his being relieved from court-martial duty at Little Rock Bks., Ark. Par. 7, S. O. 276, A. G. O., Washington, November 26, 1888.

Capt. Edward B. Moseley, Asst. Surgeon, leave of absence granted in S. O. 67, November 11, 1888, Div. of the Pacific, is extended three months, by direction of the Secretary of War. Par. 13, S. O. 275, A. G. O., November 24, 1888.

Capt. Robert B. Benham, Asst. Surgeon U. S. A., Ft. Laramie, Wyo., is hereby granted leave of absence for one month. Par. 1, S. O. 111, Hdqrs. Dept. of the Platte, November 24, 1888.

Capt. John Van R. Hoff, Asst. Surgeon, leave of absence granted in S. O. 134, November 1, 1888, Dept. of the Missouri, is extended one month, by direction of the

Secretary of War. Par. 3, S. O. 274, A. G. O., Washington, November 23, 1888.

Capt. William F. Carter, Asst. Surgeon U. S. Army, is granted leave of absence for one month. Par. 4, S. O. 116, Hdqrs. Dept. of Texas, San Antonio, November 12, 1888.

First Lieut. Paul Clendenin, Asst. Surgeon U. S. Army, is granted leave of absence for one month, to take effect December 4, 1888. Par. 3, S. O. 116, Hdqrs. Dept. of Texas, San Antonio, November 12, 1888.

Official List of Changes in the Medical Corps of the U. S. Navy for the Week Ending December 1, 1888.

Surgeon J. H. Gaines, detached from the "Dolphin" and ordered home.

P. A. Surgeon Frank Henderson, detached from the "Pensacola" and to the "Dolphin."

Surgeon Wm. H. Jones, detached from the "Richmond" and to the "Pensacola."

P. A. Surgeon A. C. H. Russell, detached from the Naval Academy and to the "Wabash."

P. A. Surgeon N. H. Drake, detached from the "St. Mary's" and to the Coast Survey.

P. A. Surgeon H. W. Whitaker, ordered to the nautical school ship "St. Mary's."

P. A. Surgeon D. O. Lewis, detached from the Coast Survey and to the Naval Academy.

Asst. Surgeon A. R. Wentworth, ordered for examination preliminary to promotion.

Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine Hospital Service, for the Five Weeks Ending November 24, 1888.

Surgeon Walter Wyman, from New York, N. Y., to Washington, D. C. November 16, 1888.

Surgeon W. H. Long, from Detroit, Mich., to Cincinnati, O. November 16, 1888.

Surgeon C. S. D. Fessenden, from Norfolk, Va., to Louisville, Ky. November 16, 1888.

Surgeon Geo. Purviance, from Cincinnati, O., to Baltimore, Md. November 16, 1888.

Surgeon H. W. Austin, from Chicago, Ill., to Milwaukee, Wis. November 17, 1888.

Surgeon John Godfrey, from Louisville, Ky., to Milwaukee, Wis. November 14, 1888.

Surgeon John Godfrey, from Louisville, Ky., to New York, N. Y. November 16, 1888.

P. A. Surgeon F. W. Mead, from Baltimore, Md., to Norfolk, Va. November 16, 1888.

P. A. Surgeon John Guitcras, from Camp Perry, Fla., to Charleston, S. C. November 15, 1888.

P. A. Surgeon S. C. Devan, from Savannah, Ga., to Washington, D. C. November 15, 1888.

P. A. Surgeon F. M. Urquhart, from Live Oak, Fla., to Dupont, Ga. November 3, 1888.

P. A. Surgeon S. D. Brooks, from Wilmington, N. C., to Savannah, Ga. November 15, 1888.

Asst. Surgeon J. B. Stoner, from Charleston, S. C., to Wilmington, N. C. November 15, 1888.

Surgeon P. H. Bailhache, granted leave of absence for twenty days. November 24, 1888.

Surgeon W. H. Long, granted leave of absence for sixteen days. November 21, 1888.

Asst. Surgeon W. P. McIntosh, granted leave of absence for thirty days. October 24, 1888.

Asst. Surgeon G. M. Magruder, granted leave of absence for thirty days. November 23, 1888.

Asst. Surgeon J. O. Cobb, granted leave of absence for twenty days. November 20, 1888.

Asst. Surgeon H. D. Geddings, granted leave of absence for thirty days. November 1, 1888.

Surgeons Walter Wyman, H. W. Austin, John Godfrey, representatives at meeting of American Public Health Association.

P. A. Surgeon W. P. McIntosh, promoted and appointed P. A. Surgeon November 21, 1888.

ETIOLOGY OF THE IRREGULARITIES OF THE TEETH AND JAWS.

ARREST OF DEVELOPMENT OF THE SUPERIOR MAXILLA.

Read in the Section on Dental and Oral Surgery, at the Thirty-ninth Annual Meeting of the American Medical Association, May, 1888.

BY E. S. TALBOT, M.D., D.D.S.,
OF CHICAGO, ILL.

The subject of the etiology of irregularities of the teeth is so comprehensive and so replete with points of interest, that it is obviously impossible for one to enter into minutiae within the limits of a single paper. I have therefore deemed it best to prepare a series of papers, in which an attempt will be made to present in an intelligible manner the conclusions formed during an extensive experience in the examination and study of the mouths of strong and well constituted persons, of the mouths of the insane, idiotic, deaf and dumb, and blind, and of models of various deformities of the jaws and teeth. In the present paper—the first of the series—attention will be given to such irregularities as are developed coincidently with the growth of the skeleton; these being, as is well known, chiefly connected with the superior maxilla.

Irregularities of the teeth may be classed as, first: those developed with the formation of the osseous system, and due to constitutional causes; second: those produced by local causes. Irregularities which are inherited, or appear *pari passu* with the development of the osseous system, always take definite shapes and are either the result of arrested development or of inharmonious growth of the maxillary bones. Where arrested development causes deformities they assume the forms known as the saddle- and V-shaped arches, or deformities of a similar character. Where the deformities are due to local influences they may assume any shape or position, the irregularities appearing at or soon after the development of the permanent teeth. English and American authors have spoken of irregularities as congenital, or being of a congenital origin. We can readily understand that the deformity of a single tooth may be congenital, but cannot agree in the classification of an irregularity of several teeth upon

either or both jaws among congenital deformities. Congenital, according to Webster and Quain (whose definitions are generally accepted by medical men), signifies "pertaining to or existing at birth." For instance, cleft palate, hare-lip and spina bifida are congenital deformities, because they exist as entities at birth. The first teeth have not taken positions at birth, and as the permanent teeth do not appear for six years, nor assume any degree of deformity for some years after eruption, general irregularities of the permanent teeth could hardly come under Quain's definition of congenital.

In discussing the subject of irregularities of the teeth it is necessary to commence at the formation of the bones of the skeleton, taking up the different deformities in their natural order, and finishing with the simple irregularities caused by local disturbances. As already indicated, attention will be directed in the present paper chiefly to the subject of those constitutional and hereditary conditions which affect the form of the maxillary bones. The maxillary bones include that part of the upper and lower jaw to which are attached the muscles, and not the alveolar processes, which are for the purpose of retaining the crowns of the teeth while they are forming, and for the retention and support of the teeth after eruption. Anatomists speak of the two portions as one bone, but the growth and functions of the two parts differ so widely that it seems necessary to the orthodontologist to consider them as separate and distinct structures. The lateral halves of the human frame do not always correspond in weight and size. This is true of both external and internal organs. This difference in the contour of both sides of the cranium may be seen in almost every head measure taken by the latter. The feet, hands and limbs will show the same variation in the lateral halves. We should, therefore, be prepared to find not only differences in the upper and lower jaws, but changes in the lateral halves of each bone. This can be shown by taking full and accurate impressions of both jaws and mounting them upon wire articulators. By comparing first the jaws and then the lateral halves we may readily see how much variation exists in the jaw and teeth. These deformities are often so prominent that mechanical interference is necessary to

improve the appearance and the use of the teeth.

We are indebted to Mr. Langdon Down for first calling the attention of the profession to the V-shaped, saddle-shaped, and high arches in connection with the condition of idiocy. Later on, Dr. W. W. Ireland contributed largely towards our knowledge of and interest in these deformities. Both of the gentlemen named are at the head of large English institutions for the feeble-minded, and are devoting their lives to the care and training of these unfortunates. The numerous able papers pertaining to this subject which they have published, bear testimony to their experience and ability in all phases of idiocy. The most remarkable feature of their conclusions, as far as I am able to comprehend them, is their apparent recognition of the frequent existence of the three principal forms of maxillary deformity, and their failure to recognize any other forms of osseous asymmetry and irregularity in the skeletons of idiots. Such a preponderance of maxillary deformities as compared with other osseous tissues in the same class of subjects, is incomprehensible to me, and I find upon investigation that several prominent writers entertain quite different views. Drs. Kingsley, Stelwagen and White claim that the saddle- and V-shaped jaws and high arches are by no means characteristic deformities of idiots, and that they occur with no greater frequency than in other classes of patients. These authors also fail to note any especial tendency to irregularity and asymmetry of development on the part of the general osseous tissues of idiots.

In extensive personal examinations through various institutions for idiots, deaf and dumb, and blind, the conditions which have been observed may be classified as, first: those which are developed with the growth of the individual and may be properly called constitutional; and second: those produced by local influences. I found not only the three principal deformities of the jaws, but other irregularities, to be quite common. Among them were cases of large jaws, protrusion of the upper and lower jaws, high arch, V- and partially V-shaped arches, saddle-shaped arches, small teeth, and arrested development of the jaw bones, especially the superior maxilla. While making these examinations I observed in many of the individuals examined deformities and arrest of development with asymmetry of different members of the body. From these examinations I believe myself warranted in the assertion, that a much larger percentage of deformities of the teeth and jaws exists among a given number of imbeciles, deaf and dumb, and blind, than in the same number of normal individuals; the various conditions being the result either of arrested development, inharmonious development, or excessive growth. When we consider what special conditions constitute the entity termed idiocy, such occurrences are not at all surprising, idiocy being a general

condition. Dr. Shuttleworth has aptly described "idiocy as a vice of the entire organism, an affection not only of the nervous system, but of the functions generally of organic life. Oftentimes the whole bodily conformation bears the impress of idiocy, and not only the lineaments of the face, which by its intelligence should reflect the Divine image, but also the form of the limbs, and especially of that masterpiece of mechanism, the human hand, are sadly marred." By studying the causes and effects of idiocy we may be able to find the relations between it and abnormalities of the maxillary bone. According to one of the best authorities (Dr. W. W. Ireland) "idiocy is mental deficiency or extreme stupidity, depending upon malnutrition or disease of the nerve centres, occurring either before birth, or before the evolution of the mental faculties in childhood." From this definition we see that arrested or imperfect development of nervous tissue may take place either *in utero* or soon after birth, before the organs and tissues are developed perfectly. Such perversions of development do not confine themselves to nerve tissue alone, but may occur in any or all the tissues of the body, having apparently an especial predilection for the osseous system.

It is obvious that any condition of malnutrition, particularly if existing during the period of embryonal and infantile growth and development, which is sufficiently marked to cause perversion of growth in the complex nervous centres, must necessarily affect the tissues in general. Nervous tissues have relatively greater vitality than the other tissues of the body, and every physician knows that the brain and spinal cord will often functionate after the other structures of the body have been seriously impaired by disease. Nowhere in the range of medicine is the old adage of *mens sana in corpore sano* more aptly illustrated than in the general make-up of the idiot. He is an imperfect creation and, as far as my observations go, often thrown together in a manner quite suggestive of the absence of design.

Consanguinity in its Relation to Deformities in General.—Consanguineous marriages not infrequently result in mental aberrations in the progeny. Dr. Howe states that in 17 families the heads of which were related by blood and intermarried, the result was fearful. Most of the parents were intemperate or scrofulous, and some combined both evils, so that it must be admitted that there were other causes to increase the probability of infirm offspring, besides consanguinity. There were born in these families 95 children, of whom 44 were idiots, 12 were scrofulous and puny, one was deaf and one was a dwarf. In some of the families all the children were either idiotic or very scrofulous and puny. In one family of 8 children 5 were idiotic. The commissioners of idiocy in Connecticut found in 160 cases of idiocy 20 which apparently resulted from consanguineous

marriages. Of these 12 were children of first cousins, 3 of second cousins, 1 of third and 4 of distant relations. Dr. Langdon Down found that out of 753 male idiots 33 were the offspring of first cousins, 3 cases of second cousins, and 4 of third cousins; in all 40 cases out of 753, or rather more than 5 per cent. Of the 295 females, 13 were the children of first cousins, 3 of second cousins, and 4 of third cousins; in all 20 among 295, or little less than 7 per cent. His researches show that in England at least every fourteenth idiot is the child of cousins. The majority of cases of idiocy appear at birth, and many such may be traced to habits or tendencies of ancestors. Often it is difficult to determine in what generation the germs of the disease were planted. Ludwig Dahl, of Norway, in his work on insanity, shows by means of a genealogical tree, how an apparently healthy couple may have children, grandchildren, and great-grandchildren affected with idiocy and insanity.

In reviewing the field of possible causes of idiocy, I am greatly impressed by the apparent influence of consanguineous marriages. Dr. S. M. Bemis, of Louisville, Ky., has found through his examination of statistics supplied by a number of physicians, that among 2,778 children, the fruits of intermarriage of first cousins, 793 were normal; 117 deaf and dumb; 63 blind; 231 idiotic; 24 insane; 44 epileptic; 189 scrofulous; 53 deformed; 637 died early.

Scrofula.—The most common lesion accompanying idiocy is some form of scrofula, such as strumous ulcers, skin eruptions, abscesses, enlarged and suppurating glands, diseases of the eye and ear, these diseases being quite general attendants of idiocy. A very large proportion of persons affected with idiocy die of consumption of the lungs, which is of all diseases most often associated with what may be termed a defective make-up. Dr. Ireland says that at least two-thirds of the idiot class are of scrofulous constitutions. "Is arrested development of brain tissue the result of scrofula, or do scrofula and idiocy proceed from a common cause?" is a question often propounded to physicians. In the light of recent observations, I am personally of the opinion that when the two conditions are associated, they are dependent upon a common cause—never, in my opinion, do they bear the relation to each other of cause and effect. The teeth, as we well know, are affected in their development and growth by scrofula and other constitutional defects. The other organs and tissues of the body may not outwardly show such defects as plainly as do the teeth, but the result of any constitutional disease will nevertheless be apt to exist in a form quite as markedly pathological.

Drunkenness in Parents.—There is a wide variance of opinion among medical men, regarding the probable influence of intemperance of parents

in the production of idiocy and allied conditions in their offspring. Dr. Langdon Down is emphatic in his opinion that drunkenness at the time of conception is liable to produce serious results upon the brain of the child. Ludwig Dahl believes that the abuse of brandy in both father and mother is one cause of the large number of idiots in Norway. On the other hand Dr. C. T. Wilber, of the Illinois State Asylum for idiots, states that in 365 idiotic patients 8 only claim drunken parents. Dr. Graham, Superintendent at Earlswood, Eng., also states that he found among 800 inmates of that institution, but 6 cases of idiocy which could be attributed to intemperance of parents. Whether or not drunkenness is responsible for idiocy we cannot decide, but we know positively that intemperate habits are transmitted from generation to generation, each series of progeny in the line of descent showing a lower grade of intellect. As an illustration of the probable influence of intemperance, I cannot do better than quote Dr. Shuttleworth. Considering the intimate and prolonged dependence of the child upon the mother during gestation and nursing, one would suppose *a priori* that maternal rather than paternal drunkenness would count most in production of idiocy.

In the cases which I have tabulated, drunken fathers preponderate in a majority of 13 to 4. Possibly the mental anxiety entailed upon the wife by a drunken husband during the impressionable period of pregnancy may in part explain the discrepancy. Whatever the direct effect of drink upon the fœtus *in utero*, there is little doubt that such nursing as a child is likely to obtain from a drunken mother will intensify any predisposition to mental defect. The baneful practice of giving infants alcoholic drinks seems to prevail to a great extent in Sweden and Norway. Such practice may in part account for the extensive prevalence of idiocy and juvenile insanity in Scandinavia as described by Ludwig Dahl.

Prenatal Influence and Intra-uterine Education.—It is unquestionably a fact that a fright to the mother during pregnancy is occasionally a cause of idiocy in children. Women instinctively shrink from anything which would produce a shock or special mental impression during the period of gestation, fearing for both the mental and physical welfare of the child. Strange to say, the same maternal instinct prevails with the brute creation. Dr. G. H. Fisher has written a complete history of the "Literature, Classification and Description of Human and Brute Monstrosities," including the so-called Parasitic Monster known as "Fœtus in Fœtu," and the various supernumerary formations of parts and organs which are familiar to medical men.¹

¹ "Many interesting cases are given by this author, including deformities of the upper and lower extremities and internal organs. He states positively that the lower animals may become insane.

The result of the various lesions and pre-natal impressions already mentioned is not only mental in character, but we invariably find arrest of development of brain substance in idiots, imbeciles and feeble-minded children, the different terms indicating the degree of mental development. It is to be observed that a majority of these cases are affected by impressions made upon the fœtus *in utero* through the influence of the parents. A few cases, however, are mentioned as resulting from diseases or injuries occurring soon after birth, or in childhood. If arrest of development of brain tissue occurs *in utero*, or in early childhood, other organs or tissues of the body are likely to be similarly affected. The brain of the idiot is lighter and has fewer convolutions than the normal brain, and also differs in that the convolutions of the idiot's brain correspond on both sides, like the monkey's, while they vary in the normal human brain. The anterior lobes of the cerebral hemispheres are imperfectly developed, and where the head is unusually small the antero-posterior diameter of the cerebral hemispheres is shortened. Irregularity of the two halves of the brain is quite commonly observed.

The cerebellum, pons Varolii, and medulla oblongata, are smaller than normal with almost perfect asymmetry. Not infrequently portions of the brain are altogether absent. Absence of the entire cerebellum and a rudimentary condition of one or both obliary bodies, peduncles, optichalami and corpora striata having been noticed. Griesinger, in his work on mental diseases, mentions a number of interesting cases, one of which we will cite. The brain examined was that of a girl 17 years of age, who presented the highest type of idiocy, in conjunction with a generally defective physique. The conditions present were very interesting and may be briefly described as follows: The middle free portion of the corpus collosum was entirely absent, as were also apparently the septum and the middle portion of the fornix. The anterior and white commissures of the gyrus fornicatus were decidedly rudimentary. The convolutions presented an abnormal grouping and the Island of Reil was greatly atrophied. Some of the convolutions were entirely absent. The lobes of the cerebellum were asymmetrical.

Dr. A. Wilmarth, of the Penn. Institute of Feeble-Minded Children, says: "In six brains the Island of Reil was exposed through the defec-

tive development of the third frontal convolution; in four cases on two side, in two on one side only. In 18 brains 6 were found where the cerebrum failed to cover the cerebellum from one-eighth to five-eighths of an inch."

I could quote indefinitely from eminent authorities at home and abroad to show that not only are the different structures of the brain of the average idiot atrophied, and often entirely wanting, but that diminution of weight is the rule. Enough cases have been cited to give a general idea of the defects in anatomical structure of the brain of idiots.

Having determined the constant relation of defective cerebral development to idiocy, it remains to be proven whether the defective condition is a special one affecting the brain only, or is an integral part of the generally defective, or mal-development, or at least of a general tendency toward such perversions of growth. When we take into consideration the fact that the fœtus is developed in two lateral halves, which may or may not develop harmoniously and may or may not fuse together properly, it becomes logical to presume that any influence which tends to produce inharmony and asymmetry of growth in one part of the body, *e. g.*, the brain, must necessarily tend to produce the same conditions in other portions of the fetal halves, providing such influence is not a purely local one. The causes of idiocy not being local, but general, the inference is obvious. It is astonishing to me that the superintendents of institutions for feeble-minded have made so little note of the asymmetrical relations of the two lateral halves of the body, in the cases under their care. Personally, I am of the opinion that harmony of members does not generally prevail in the anatomy of the idiot. In examining the inmates of various institutions I was struck with the numerous examples of arrested development, hypertrophy and asymmetry of upper and lower extremities. These abnormal conditions accord with the types of cerebral mal-development already cited. The following cases from other sources confirm the accuracy of these observations:

"Boy of 5½ years. Admitted into the Liverpool Infirmary for Children October 15th, 1878. Weight 10½ lbs.; height 29 inches; intelligence very limited; can utter no articulate sound; eyes large and well-developed, yet he is undoubtedly blind. Sense of hearing apparently normal. He has all his first teeth, but makes no attempt to masticate his food. Forehead does not recede, head is proportionate to size of body; circumference over the occipital protuberance and eyebrows 16 inches. Cannot sit up, the back below the neck being rigid and arched in the lumbar region from tonic contraction of the spinal muscles, pro-

and that heredity and pre-natal shocks have much to do in producing these conditions.

"Innumerable cases of pre-natal shocks producing idiocy where the parents were both apparently healthy are on record. In one case the news of the loss of the husband at sea had the effect of impairing the intellect of the unborn child; again, the same result occurred in another case as a result of fright occasioned by a team of horses running away with the mother when well along *in utero* gestation. Baron Percy, a French military surgeon, observed that out of 62 children whose mothers had been exposed to the terrors of a tremendous cannonade at the siege of Laudau, in 1793, 16 died at the instant of birth; 33 languished from 8 to 10 months and then died before the age of 5 years; and 2 came into the world with numerous fractures of the bones of the limbs."—Trans. N. Y. State Med. Soc. 1865 to '68.

NOTE.—Rawdon, H. G. "Case of dwarfed growth associated with idiocy and congenital tonic contractions of the muscles of the spine and limbs."—British Medical Journal, London, 1879, 1, 386.

ducing a condition resembling opisthotonos. The upper extremities are in a state of rigidity, the limbs have a wasted and shriveled appearance, but the face is not thin. The child has evidently been well cared for. There is no tendency to rickets. Facial and cervical muscles are unaffected.

"The child was affected as described from his birth; was a twin, but only one-third the size of his fellow twin. He cut his teeth at the usual period. Has had no convulsion or disease of any kind since his birth. He was suckled. Father and mother are healthy and live in the country and their children before and after the birth of this one were healthy and well developed.

"I have thought this case might be of interest to the profession. It certainly seems a curious fact that I should not have been able to discover any report or notice of a case at all similar to this one, and yet I cannot doubt that such cases have from time to time occurred. The case may, perhaps, be regarded as one of intra-uterine blight, but why, or when it took place we can have no means of judging."

(2) Mazier (Edmund).

"On arrest of development in idiocy."

Paris Thesis, No. 452, Paris, 1879.

General conclusions of author:

1. Idiocy consists in an arrest of cerebral development primarily of the nerve centres.
2. This arrest of development may appear at any time of life, uterine or extra-uterine.
3. The organs whose development is incomplete at the time when the arrest of cerebral development occurs are also affected in their development.

4. The anomalies thus resulting consists in the persistence of one of the transitory or rudimental forms through which the body must pass before reaching its complete development.

5. The arrest of development of an organ interferes with its functions, and from this results malformations and numerous organic deviations which constitute a secondary series of anomalies only mediately allied to idiocy.

Obs. 1.—E. P., æt. 16 years, natural child, twin. Had ocular hæmorrhage soon after birth; convulsions till the age of 7; percutient cephalalgia; began to walk when 2 years old; could speak a little earlier.

Cranium: Antero-posterior diameter 0.18 m, transverse diameter 0.15.

Face: Total length 0.155, occipito mental diam. 0.278. Mouth open. Tongue always protruded between the teeth. Palatine arch is deep and oval.

Genital organs are rudimentary.

Mental condition: Voracious glutton; is susceptible of education, having learned to read; cannot write or count. Tries to be useful.

Obs. 2.—P. S., æt. 18, idiot. Mother hysterical,

grandfather died of apoplexy, grandmother was a drunkard and died of phthisis. Forehead narrow, temples hollowed. Microcephalic. Began to speak and walk very late. Is very clumsy; has had convulsions; is frequently angered. Epileptic vertigo. Chronic ophthalmia. Eyes quite separated. Dentition defective; superior dental arch is triangular. Teeth are disposed in three rows and are prominent and projecting. Ears small. Nose greatly developed and arched. Forehead receding and depressed.

Cranium: Antero post., diam. 0.170, transverse diam. 0.137.

Face: Total length 0.127. Extl. orbital line 0.107. Defective formation of the feet and hands, which are flat; thumbs are thick, short and spatula-like.

Penis well developed; pubis hairy; no testicles in scrotum, but can be felt in the inguinal canal on each side.

Mental condition: Masturbator. Does not understand anything. Impulsive, violent, cynical.

Obs. 3.—P. P., æt. 17. Idiot in the 2d degree. Congenital club-foot. At the age of 3 years had meningitis, with convulsions for 15 days, and consequent permanent strabismus. Began to walk at 4, and to speak, very late and with great difficulty. Has had variola, typhoid fever, pleurisy and scrofula.

Head: Well formed, hearing good.

Face: Only two incisors in upper maxillary; no canines, three molars on each side. Inferior maxillary is narrowed at a level with the premolars (permanent), two canines, gums fungous, spongy and bleeding.

Hands large and purple. Atrophy of testicles. Penis normal.

Obs. 4.—G. D., æt. 21 years. Microcephalic, can speak and read. Cranium rudimentary.

Ant. post. diam. 0.147, transverse diam. 0.118. Face: total length 0.122. Occipito mental 0.202, external orbital line 0.097; opening of superior dental arch on a level with the first premolar, 0.027.

Ears well developed.

The superior dental arch is contracted at a level with the molars, and thence divergent, teeth carious. Finger-nails curved like claws. Thumb of right hand is upon the same plane as the other fingers, and its dorsal face is turned backwards. Feet long, flat, narrow and misshapen.

Mental condition: Intellectual faculties nil. Tries to attract attention. Has had instincts.

Obs. 5.—L. L., æt. 13. Imbecile. Scrofulous constitution. Double convergent; strabismus very marked. Ears largely developed. Palatine arch high, regularly oval and deep.

Superior maxilla large and thick, and its teeth carious. No canines. Tonsils large, with atrophy of uvula. Genital organs atrophied, single tes-

ticle in scrotum. Belly large and pendulous. Is able to read and write some. Has had instincts and is easily angered.

Obs. 6.—G. S. æt. 16, imbecile, deaf, internal strabismus.

Head normal. Face long, 0.152, width 1.075, occipito mental diam. 0.233; dental arch at a level with the first molar, 0.022.

Ears long. Mouth always open.

Superior dental arch narrowed, palatine arch oval and deep, tonsils enormous, teeth carious and irregularly disposed. Superior prognathism. Lips thick, the inferior is hanging. Intellect susceptible of development. Has had instincts.

Obs. 7.—L. O., æt. 16. Complete idiot, deaf and dumb. Head quite large. Eyes most always closed; strabismus. Convulsions four days after birth, daily attacks till the age of 18 months. Left hemiplegia and right hemichorea. Could walk at 2½ years. Has a deaf sister who has a hare lip. Ptyalism: face asymmetric, more developed on right side. Cranium: Ant. post. diam. 0.165, transverse 0.135. Intellectual faculties nil.

Obs. 8.—F. N., æt. 15. Scrofulous constitution. Microcephalic. Cranium: Post. diam. 0.145, transverse diam. 0.127. Face: Length 0.126, occipito mental diam. 0.222, external orbital line 0.101.

Dental arch on a level with first premolar.

Chronic blepharitis.

Mental condition: can speak, hear, and reads a little, but cannot write nor count. Incapable of the least mental effort.

Obs. 9.—A. B., æt. 10. Superior and inferior prognathism, still has his first teeth which are quite regular. Intellectual faculties nil.

N. B. The measurements are in the metric system.

There are seven other cases almost precisely similar to the above, given in the same work, but it is unnecessary to quote them.

A paper by Dr. G. E. Shuttleworth, England, presented before the International Health Exhibition, London, Aug. 2, 1884, upon "The Health and Physical Development of Idiots as compared with Mentally Sound Children of the same Age," he says, "Many idiots are undoubtedly small at birth, not a few have been brought into the world prematurely, but in nearly all, imperfections of functions interfere with due nutrition and development, as the following table will demonstrate:

Report of Cases of Arrested Development and Excessive Growth of all the Tissues, in Connection with Idiocy, Imbecile and Feeble-minded Children.

Table shows the Relative Mean Stature and Weight of the general population and of 1,209 Idiots and Imbeciles in Earlswood, Royal Albert, and Larbert Asylums.

Age last Birthday.	HEIGHT.				WEIGHT.			
	General Population.		Idiots and Imbeciles.		General Population.		Idiots and Imbeciles.

24	68.25	63.45	65.0	60.25	150.0	124.8	123.5	108.5
25-30	67.75	62.02	64.75	59.75	151.2	120.0	123.0	109.0
30-40	68.0	62.15	65.0	60.0	152.5	120.8	123.5	109.0
40-50	68.25	62.28	65.25	60.25	153.7	121.6	124.0	109.0
50-60	68.5	62.41	65.5	60.5	155.0	122.4	124.5	109.0

It will be observed that idiots are shorter than the general population: at 5 years, by 1 inch; at 10 years, by 2 inches; at 15, by 3 inches; at 20, by 3 inches. While, as regards weight, male idiots are lighter than the general population: at 8 years, by 4½ pounds; at 10 years, by 6 pounds; at 15 years, by 8 pounds; at 20 years, by 23½ pounds, the disparity being greater in the male than in the female sex. It appears that the relative rate of growth of the two sexes of idiot children follows the same rule as that of normal children, and is subject to the same variations at the age of puberty, for two years preceding which the growth of girls is in excess of that of boys.

ABNORMALLY SHAPED HEADS.

If the mental capacity could in all instances be measured by the size and form of the head, many among the idiotic would rank high. The shape and size of the skull is indicative of the mind only in a general way, the feeble minded being about equally divided between abnormally large and small heads. The measurement of the ordinary well-balanced head ranges from 20 to 36 inches in circumference, and that of the idiotic head from 12 to 26 inches. Opinions vary in regard to the average size of the microcephalic idiots, some claiming that all heads of 16 inches and under come under this class, and others that 13 inches in circumference is the average microcephalic head, while upon the other hand, all heads which measure more than 36 inches in circumference would be considered either macrocephalic or hydrocephalic.

The extreme cases are comparatively few in the institutions. Out of 600 inmates of the

Pennsylvania Institution, at Elwyn, which I examined with the assistance of the superintendent, Dr. J. N. Kerlin, and Dr. Wilmarth, I found but 28 microcephalic, 24 macrocephalic and 3 hydrocephalic cases. We shall find these extreme cases exceedingly interesting in the study of the etiology of irregularities of the teeth, and shall give special attention to their relations later. There is a certain size of the head, below which an individual must be an idiot. Voisin says, "that the proper exercise of the intellectual qualities is impossible with a head of from 11 to 13 inches in circumference, and a measurement of 8 to 9 inches from the root of the nose to the posterior border of the occipital bone." Irregularities in the external surface of the cranium predominate in every idiotic head, and in such variety that no two heads are found alike. These conditions show a want of development of the brain. The brain substance being the first to obtain its growth, the cranial bones are moulded about it, and are in a manner supported by it until the sutures have united. If the brain be slow in developing and shaping, ossification of the sutures is retarded; should the brain or parts of it be retarded in growth, the cranium would be either microcephalic or asymmetrical in its development. Again, inharmonious closure of sutures may also produce unilateral contractions of the bones of the head. I do not wish to convey the idea, however, that asymmetry in the cranium is always the result of malformation of brain tissue, as by far the majority of cases result from arrested development or interruption in the growth of bone tissue. *Per contra*, I am well aware that perfectly symmetrical heads are rare in even normal individuals. The diagrams in possession of our hatters tell a woful tale, not at all flattering to our racial self-conceit! This retarded growth may result from constitutional disturbances acting unfavorably upon general nutrition, or from inflammatory conditions of the osteophytic membrane which may take place *in utero*, thus prematurely closing the sutures. There is no law governing the development of the brain and the closing of the cranial sutures. Those bones, the sutures of which close before the proper time, will be narrowed at the point of premature fusion. It is reasonable to expect, that when bones prematurely ossify at one part of the cranium, dilatation will take place directly opposite, as the brain grows in the direction of the least resistance. This explains many peculiar deformities of the head; again, if the majority of the sutures ossify prematurely, microcephalus may result. It appears reasonable, also, to infer that the shape of the basis cranii will be affected in a similar manner by too early or too late ossification. These changes are caused by improper nutrition of the bones and cartilage. A knowledge of this fact gives us a clear conception of

the relation which various general conditions bear to idiocy and imperfect development in general. The influence of such perversion of nutrition as are produced by syphilis, tuberculosis, struma and intemperance over the ossification and growth of bone is a most potent one. The shape of the base of the skull and the contour of the face depend largely upon the ossification of the sutures. When ossification of the cartilages occurs early, a shortening of the basis cranii results. Especially is this the case when premature ossification occurs in connection with the sphenoid bone. The age, when the basilar portion ossifies in a normal subject is from 15 to 20 years. Thus too early ossification naturally produces a shortening in the antero-posterior direction which cause serious deformities in the shape of the face, and an abnormal curvature at the base of the brain. The superior maxillary bones are attached to the bones of the head and face by eight articulations, and as the ossification of the sutures occurs at about the same time as the ossification of the sutures of the basis cranii, the same influences which affect the cranium must also affect the superior maxilla. These conditions may account for family features not presenting themselves until middle age. This is a strong argument in favor of postponing the operation of regulating teeth until the contour of the face has been permanently established. When there is inflammation of the membrane *in utero* (which is of common occurrence), the sutures ossify before or soon after birth, and as a result the base of the cranium will assume and remain in, an undeveloped condition, causing the face to present an abnormal shape and size, which will broaden the face, throw the cheek bones out prominently, make the nose broad, flat and sunken, and extend the space between the eyes, giving as a whole a face void of expression. When the sutures at the base of the skull ossify normally the antero-posterior diameter is longer, the base of the cranium is more angular, the features sharper, with the eyes closely set, and a face full of expression. The sphenoid bone does not attain its full size until from the 25th to the 30th year of age.

I am of opinion that when the bones at the basis cranii ossify before, or shortly after birth, the superior maxilla and septum nasi assume a decidedly unnatural form. Dr. Oakley Coles, in his work upon "Deformities of the Mouth," ascribes the different deformities of the jaw to premature ossification either of the sutures or the basis cranii, thus he says, "that the deformity known as inter-maxillary prognathism is the result of a force operating on the inter-maxillary bone, such force originating in the body of the sphenoid and being transmitted by the intervening nasal septum."

He says, also, page 95, "After carefully exam-

ining the works of various writers on the subject of microcephalic idiocy, there seems sufficient evidence to justify the belief that premature ossification of the sutures is the rule in a majority of cases of microcephalus, and we may, therefore, assume if we cannot absolutely conclude, that this influence operates powerfully in the production of the dental deformity known as the lambdoid jaw" or V-shaped arch.

While, as has already been observed, I believe that premature ossification of the sutures and basis cranii is followed by deformities of the jaw and septum nasi, I do not think that they bear to each other the relation of cause and effect. In this I beg leave to differ with Dr. Coles. It is unnecessary to expatiate upon this subject in the present paper, as it will be the principal topic for discussion in another which I hope to present later on.

RÉSUMÉ.

1. Irregularities of the teeth cannot be justly said to be of congenital origin since they do not exist at birth.

2. Irregularities of the teeth cannot occur until they have erupted, and thus shown their relation to each other and to the jaw.

3. Irregularities of the teeth, which I have designated constitutional, prevail to a greater extent among the idiotic, deaf and dumb, and blind, than among an equal number of strong and healthy persons.

4. It may be seen that not only is the brain matter deficient in the feeble-minded, but, as I have noted, many cases are seen which demonstrate that the osseous system is also generally defective.

5. Arrest of development is the result of malnutrition during embryonal and infantile growth influenced by consanguineous marriages, scrofula, drunkenness in parents, pre-natal influences, intra-uterine education and constitutional diseases, or of inflammation of the osteophytic membranes *in utero*.

6. Irregularities of the teeth do not exist among normal or large jaws, while among those who have abnormally small jaws, the majority have irregular teeth.

7. When premature ossification of the sutures at the basis cranii takes place, the antero-posterior diameter is shortened, producing arrested development of the superior maxilla.

8. When the bone tissue is arrested in development from malnutrition, the maxillary bones are also affected.

9. When arrested, development of the superior maxilla occurs, the face often presents a sunken appearance at the angle and root of the nose, with the nose broadened and the inferior maxilla prominent.

10. In another paper I shall attempt to prove

that the irregularities of the teeth, called constitutional, are the results of small maxilla, and that Dr. Hammond's future man will not only lack hair and teeth, but the superior maxilla will gradually decrease in size and eventually become rudimentary.

DR. J. S. MARSHALL, Chicago: I have listened with great interest to the subject just presented by my friend, Dr. Talbot. I believe he is correct when he says the causes of irregularities are: "First, those developed with the formation of the osseous system and due to constitutional causes; and, Second, those produced by local causes;" but cannot agree with him in his objections to the use of the term *congenital*, as used by the English authors quoted, when they say, certain forms of irregularities are congenital, or of congenital origin. The author would confine the term to very narrow limits,—to conditions which are present and discernible at birth only. The inherited small superior maxilla, which upon the eruption of the permanent teeth cause irregularities is, nevertheless, a congenital defect of conformation, though the evidence of this may not be at first apparent. I can therefore see no impropriety in this use of the term, and I think the etymology of the word will bear out the correctness of its use in this connection. Congenital causes would therefore be those which occur during generation, and may arise from hereditary predisposition, or inherited tendencies or defective conformation. Acquired causes would be those which occur after

birth, the result of disease or accident. The terms congenital and acquired, would seem to cover the subject as completely as could be desired.

The special point in the paper, however, which interested me most is that in which he claims the superior maxillæ are gradually decreasing in size and that eventually they will become rudimentary. I am not prepared to admit the correctness of these views. The thought is repulsive. What would such a condition mean? Hideous deformity. The marring of features which God created in his own image, and I cannot believe that He would afterwards so disfigure his handiwork. I am willing to admit, however, that I have seen a goodly number of such cases as the author refers to; but these were cases in which the individual had inherited the small maxillæ of one parent with the large teeth of the other, or were the result of arrested development caused by congenital or acquired idiocy.

The first named cause of this form of defective conformation I think is more commonly seen in America than elsewhere, and is due to the effects of the intermarriage of individuals from so many different races and nations, who have been brought together through immigration, under the same social system.

The Caucasian race is divided into a number of quite distinct families or national types; the English, the German, the Scandinavian, the Irish, etc., and each has a peculiar cast or type of features which indicate to which of these nations it belongs, while the size and shape of the maxillæ play a very important part in determining the type. The alveolar arch of the English forms very nearly one-half of an ellipse; in the German the arch is broader through the canine region, as is also that of the Scandinavian, and approaches more nearly a half circle, while in the Irish the curve is flattened in the incisive region and quite angular in the region of the cuspids. These types of features are all so marked as to be readily distinguished by even the casual observer. They are national peculiarities and will remain distinctive so long as miscegenation is not practiced to any great extent, for they are the natural result of centuries of intermarriage or breeding with people of the same type.

America, or more correctly speaking, the United States of America, cannot yet boast of a type of face that can be strictly called American. The features of the people are in a transition state. The mixture of blood has been so constant and so diverse, ever since the settlement of the country, that the original national peculiarities of features of the various nations represented are gradually being modified.

In Virginia, which was settled by the English and whose people have kept the original blood tolerably pure, we find a type which differs but

slightly from that of their English cousins, no more so than might be expected from the change of environment. In New England where the mixture of blood was quite diverse, there is seen an effort upon the part of Nature to establish a national type; but this is only the beginning. Two centuries is not time enough to assimilate and remodel such a heterogeneous mixture of conflicting elements. The crossing of races of men changes the size, form, mental capacity and physical endurance. In the crossing of distinct races, as for instance the Anglo-Saxon with the Negro, the size, form and mental capacity of the lower order may be improved, but the physical endurance (to labor or resist disease) has been lowered. This fact was generally recognized by the slave buyers before the abolition of slavery in this country, and consequently they never bought mulattoes for hard work in the rice fields or upon sugar plantations. On the other hand, the Anglo-Saxon element is not improved by the admixture of Negro blood.

Breeders of fast horses never cross their stock with an inferior breed—cart horses, Norman, for instance, but in order to improve the speed, form and endurance, they chose the finest animals of the same stock or general type, carefully selecting those having the finest points and which complement each other. In this way the stock is gradually improved in all those characteristics most desirable. This is known as selective breeding, but if confined to too narrow limits a few generations only is required before the stock begins to degenerate. Marked illustrations of this in the human family may be found in the degeneration of some of the royal and noble families of Europe, where, for political reasons, or for the sake of entailing property, they have intermarried for several generations. The insane asylums and institutions for the feeble minded give the result.

The author also says that "the teeth retain the same size and shape that they had 3,000 years ago." This, I believe, is in a relative sense true, but I cannot believe that the superior maxillæ on the other hand are growing smaller and the teeth retaining the usual size. I think he has made the mistake of drawing conclusions from isolated cases and conditions which are only transitory, steps in the processes of Nature in establishing and perfecting a new type. As I said before, we have no national type of features in America, and it will require centuries to produce one, but when that type shall have been perfected all its parts will be in harmony; there will be no such deformed physiognomy as that pictured in the paper, but rather a higher type of Anglo-Saxon beauty.

The Anglo-Saxon is the dominant race and destined to rule the world. It is stamping its peculiarities upon every race and nation with which it comes in contact, and is no less surely impressing its mental and physical characteristics

upon those people with whom it mixes its blood. This will account for the change taking place in the features and consequently in the maxillary bones and alveolar arches, of the inhabitants of this country.

The parent of the strongest characteristics usually dominates the character of the offspring.

This is equally true of men and the lower animals, and none the less true of the races of mankind. If the same care could be exercised in the selection of individuals desiring to enter into matrimonial relations that is always insisted upon in the selective breeding of horses, the congenital or constitutional causes of irregularities of the teeth, as well as other and graver constitutional defects, would soon pass away and the maxillary bones and the teeth would be in perfect harmony. But so long as men and women are permitted to enter the matrimonial state with no thought as to their fitness for such relations or the well-being of the offspring likely to be born to them, such deformities and constitutional defects will continue to exist, but not indefinitely. Nature will, in spite of this, through her moulding and assimilating processes, harmonize all discordant elements of feature and form, and produce in time a national type of face and jaws in which deformities of this class will no longer exist.

AN INTERESTING CASE OF FIBROMA OF THE LARYNX.

Read in the Section on Otology and Laryngology, at the Thirty-Ninth Annual Meeting of the American Medical Association, May, 1888.

BY JOSEPH EICHBERG, M.D.,
OF CINCINNATI.

W. S., the subject of this sketch, whom I present to the Section for further examination, first came under my observation on the 23d of September, of last year, with the following history: The boy, who had always enjoyed fair health, and was well developed and nourished for his years, was taken down on the 28th of June, 1887, with a very severe attack of scarlet fever, associated with diphtheritic symptoms of the most pronounced type, followed by severe hæmorrhage from the ulcerated patches. These hæmorrhages occurring during the period of convalescence required the hypodermic use of ergotin before they were finally arrested.

The convalescence having progressed so far as to permit of the patient's travelling, he left the city on the 7th of August, in company with other members of his family, and of Dr. Judkins, by whom I was subsequently called in council, and whose care and interest in the case has not flagged since its inception. The voice then, and prior to his illness, had been somewhat hoarse, though there had been no particular embarrassment of respiration.

It was intended to pass the summer at Atlantic City. So feeble had the little patient become, that he could neither feed himself, nor walk, at the time of leaving home. Within three days of his arrival at the seashore a marked improvement was noted, but there was scarcely any audible voice.

On the 18th of August, as the result, it was thought, of undue exposure, the boy was suddenly seized with most distressing spasmodic breathing, a hoarse, barking cough, and dyspnoea; so that it was feared a fresh membranous exudation had occurred in the interior of the larynx.

The difficulty of breathing gradually increasing, assistance was telegraphed for from Philadelphia, whither the boy was removed on the 21st of August, and tracheotomy was performed, under the advice of Dr. Meigs, by Dr. Wharton. So imminent seemed the danger that no time was taken to produce anæsthesia, and the carbonic acid poisoning had reached such a stage that, in his own words, he never felt the operation.

The dyspnoea was relieved at once, but the boy's strength again gave way and it was two weeks before he could leave his bed. The first attempt to withdraw the tube was made three weeks after the operation. In less than forty-five minutes the peculiar hoarse breathing again manifested itself, requiring the reinsertion of the tube. The effort to establish laryngeal breathing by plugging the orifice of the tube with a cork likewise proved unsuccessful, and the patient was then taken to an eminent laryngologist, who found the larynx "occluded at its upper orifice by morbid growth, which he presumed to be what is known as papilloma." A piece of this mass was removed by forceps for microscopic examination. This was on the 21st of September.

The boy was brought home on the following day and the first examination showed the entrance of the larynx to be almost entirely occupied by a pinkish mass, attached by a broad base to the middle and posterior part of the left ventricular band; completely overhanging the parts below, so that there was but a small chink along the right ary-epiglottic fold, through which an entering current of air could find passage.

On the 26th of September the loop of the galvano-caustic holder was passed over the growth, and the larger portion of the mass cut off with the snare without the aid of the current. Very little resistance was encountered in drawing the loop and only a slight hæmorrhage followed. The ease of division of the growth awakened some suspicion of malignancy, which was strengthened by the microscopic examination.

The portion of the tissue removed measured $3\frac{1}{8}$ inch in length, $\frac{1}{4}$ inch in width and was $\frac{5}{8}$ inch high. The microscope showed the growth to be covered with a layer of stratified pavement epithelium, consisting in some places of as many as

ten layers of cells loosely attached to the subjacent mass of the growth. "The tumor itself consists almost entirely of a young and rapidly-growing connective tissue, made up of round cells enclosed in the meshes of a finely fibrillated connective tissue.

"Distributed throughout the growth in considerable masses are glandular ducts and acini (probably from hypertrophied mucous glands). These are made up of short columnar epithelium, and their walls are infiltrated with the round-celled proliferation. The blood-vessels are not very abundant and the walls of the larger ones show some connective tissue thickening. In certain areas there are signs of breaking down, where collections of granular debris with isolated round cells and free nuclei are seen." A note was made at the time that were it not for the presence of such abundant fibrillated connective tissue there would be no hesitation in classing the growth as a round-celled sarcoma. No appearance of papillary overgrowth was anywhere manifest. The nature of the tumor was such as to lead to some fear for the outcome of the case entirely irrespective of the local obstruction occasioned by its position. The report of the fragment removed in Philadelphia, examined at the Army Medical Museum, was, in the main, identical with our own observations.

Somewhat fearful of the result, yet anxious to eradicate the growth if possible, the remaining portion of the base of the tumor was cauterized with the galvano-caustic wire on three separate occasions, and we soon had the satisfaction of seeing the continuity of normal mucous membrane restored, with no indication of a recurrence since that time.

The clearing of the larynx had not put an end to the difficulties in the management of the case. The patient had now worn his tracheal tube about seven weeks, and would not tolerate its removal, nor could he wear the cork for more than half a minute without manifesting alarming signs of dyspnoea.

In view of the possibility of other similar growths below the vocal cords, a metallic probe, suitably bent, was on two occasions (toward the end of October) passed through the tracheal wound, through the larynx and into the pharynx, until its rounded end was plainly visible. No obstruction was encountered.

Another experiment was made to free the patient from the incumbrance of the tube by recourse to intubation. It was thought that if an intubation tube could be inserted between the cords the external wound would close, and the metallic tube between the cords could then be withdrawn. Two attempts were made, both under ether. The tracheotomy tube having been withdrawn, the intubation tube was introduced into the larynx, but could not be passed below the cords. Either

from the effect of ether, or from the irritation of the instrument, or from paralysis of some of the muscles, a spasm of the glottis was set up, which rendered it impossible to push the tube down without the use of force, and this was not considered advisable.

Small localized overgrowths of granulation tissue in the track of the canula were easily controlled from time to time by the actual cautery. There was now some difficulty in obtaining a satisfactory view of the larynx owing to the depressed position of the epiglottis, a condition frequently observed after tracheotomy. The difficulty in this case was possibly increased by a slight cicatricial contraction in the left side of the larynx. When clearly seen, the larynx was found to be entirely free from neoplasms, and the left cord had resumed its normal appearance, though almost stationary in a position of adduction, the right moving slightly, but in a very limited arc.

The inner tube of the canula was now removed and the boy encouraged to use his voice, if possible, the tracheal orifice being closed by the finger, while the expiratory current passed through the fenestrum in the outer tube. Several changes were made in the position of this fenestrum, until it was found to correspond exactly with the tracheal lumen.

Faradization of the larynx was begun in the latter part of December, and has been continued with very little interruption, the sittings lasting about ten minutes twice a day. In January the patient was seen by another laryngologist, of New York, who found, in addition to what has been described, a slight swelling of the free edge and under surface of the cord.

The point of interest to the patient and his family was the withdrawal of the tube. Repeated trials with the cork had always produced a suffocative spasm, yet he was able to breathe comfortably, while his tube was being cleaned, for about ten minutes. It was evident that a nervous element entered largely into his inability to wear the cork. On the 26th of February, his attention being otherwise engaged, he wore the cork for eight minutes; that same afternoon for an hour, and, having once gained confidence in himself, for two, three, and four and a half hours at a time. Now he can keep it in place while eating and attending to his ordinary school duties.

Since the early part of March he has been taking minute doses of strychnine, which he bears very well, and latterly the tracheal end of the tube has been gradually shortened, so that it now passes just below the border of the tracheal wound.

How and when are we to get definitely rid of the tube? This is the all-important question for the patient and his friends; they find it difficult to reconcile the assurances of steady improvement constantly given by the physicians with the fact

that the boy is not yet able to dispense with his tube. The answer to the question must depend on the cause of the difficulty.

We have to consider the following possibilities:†

1. A narrowing or complete obliteration of the passages of the larynx by a growth of granulations above and around the canula.
2. An impairment or complete loss of those functions of the larynx which regulate the admission of air through the rima glottidis.
3. Adhesion of the opposed surfaces of the cords.
4. Nervousness and spasm.
5. Collapse or flattening of the tracheal walls in consequence of too extensive division of tracheal rings.
6. Cicatricial contraction of trachea about the incision and the end of the tube.

From the boy's ability to pass several hours in comparative comfort with the cork in the tube during the day, the inference is plain that the obstruction is not in the parts above the tube. Phonation is clear and fairly good; the pitch of the voice is, however, altered, owing to the peculiar conditions present. There are no granulations in the track of the tube, nor is there pain about its lower orifice. The expectoration which comes through the tube is not tinged with blood, as it would probably be were granulations present. Often this expectoration is easily expelled through the mouth.

There seems to be no great amount of cicatricial tissue about the tracheal wound, though this is sometimes present in great abundance, as in the case reported by Stenier, where the growth of fibroid tissue acquired dimensions of half an inch. No folds of mucous membrane, owing to the relaxed condition of this tissue, can be discovered by the probe or by laryngoscopic examination; and the only apparent causes that prevent the withdrawal of the tube are the condition of paresis of the abductors of the cords and the nervous element in the case.

Considerable attention has very justly been called by nearly all writers upon the subject to this last factor in the management of all cases of delayed removal of the tube. It certainly enters very considerably into the present case; and its importance was impressed upon me by a case seen about four years ago, in which there was retention of the tube after diphtheritic croup. In that instance, the child, three years of age, would not tolerate the withdrawal of the tube for more than five minutes. Efforts to substitute an intubation tube for the canula proved fruitless owing to the impossibility of inserting the tube.

The little patient went on in comparative comfort for about a year. The father, a brewery hand, returned home, one evening, strongly intoxicated. Enraged at the sight of the tube, he

withdrew it rather roughly and threw it across the room; at the same time threatening with dreadful punishment every one who should endeavor to replace it. Terrified beyond measure, forgetting about her own condition under the impulse of alarm that controlled her, the little girl breathed easily for the remainder of the evening and required no further attention.

Another case reported by Lovett,* falls into the same category. A girl three years old, had tracheotomy performed May 1, 1881, for croup. The tube was removed the seventh day, and left out for about forty minutes, when it had to be reinserted. May 15th another trial was made unsuccessfully. June 3d the trachea was stitched to the edges of the skin wound, yet the tube had to be replaced. Several other unsuccessful attempts were made to remove the tube, and the child was finally dismissed. One evening, July 19, 1883, two years after her discharge from the hospital, after the mother had cleaned the tube preparatory to replacing it, the child said: "I do not want it any more; you need not put it in," and never had any trouble.

The dependence upon the tube becomes so great in these cases that it is easy to understand the nervousness which follows any attempt at withdrawal; and the most difficult part of the treatment seems to be the establishment of self-confidence on the part of the patient himself. In very young children this may be accomplished by subterfuge, or the patient controlled by fear; in older patients, however, the difficulty is greater.

Some attention is to be paid to the disused muscles, which have become weakened through long inaction, until, as in our own case, a condition of more or less complete paralysis of the abductors result. The corking of the canula, and the use of the larynx for phonation and respiration will, doubtless, assist in overcoming this difficulty. It is true that Trousean has condemned the fenestrum in the tube as a useless and mischievous thing, as its sharp edges always cause irritation; but care in the location of the fenestrum, so that its edges have no point of contact with the soft tissue and a little mechanical skill in rounding the opening will overcome this objection.

The trying time for all the patients seems to be the period of sleep. Many succeed in passing the day very comfortably, but have paroxysms of dyspnoea as soon as the recumbent position is assumed, or when they eventually fall asleep. A certain amount of attention seems requisite to preserve the regular action of the parietic laryngeal muscles; and long continued exercise is often necessary before the desired result can be obtained.

I do not know that we can express in figures, or have any collected statistics bearing on, the proportion of cases in which the ultimate removal has been effected; but, while its withdrawal

†Tupper. Boston M. and S. Jour., 1886.

*Boston M. and S., June, 1886.

is manifestly desirable, existence can be easily maintained for long periods with the tube *in situ*. Thus Uhde³ reports a case where the canula was worn for forty years; and Brinton⁴ and Morton each mention a case of twenty years' standing. These statements contrast rather strongly with the announcement made by Mongot to the French Academy, that few children reach adult age after tracheotomy; a statement based on the great rarity of the characteristic cicatrix among a larger number of French conscripts.

There is but one point more to consider and that is the condition of the patient, after removal of the tube has been successfully accomplished. The anxiety that has attended the progress of the case, will even then not be entirely allayed, for some peril still hangs over the patient. Fleiner⁵ in an elaborate article on "Stenosis of the Trachea after Tracheotomy" mentions a number of cases, in which there was sudden dyspnea weeks or even months after the removal of the tube. At no time following its removal, until after the lapse of several months are we safe from the danger of sudden asphyxia, and the prognosis must be carefully held in reserve. Ross reports fourteen cases of polypi developing at the site of the cicatrix after tracheotomy; of these, four died before a second tracheotomy could be made; seven had a second tracheotomy (with five recoveries), two had a third operation and are still wearing the tubes. In forty cases of excessive granulation-growths from all sources, where the tube was worn for at least two months, sixteen were fatal, nineteen were cured and five are still wearing the tubes.

Dr. Lovett closes his article upon the subject with the statement that the treatment has been as varied as it has been inefficient. This is a rather discouraging view to take of the matter, and one that can hardly be sustained. Patience and perseverance, with a little help on the part of the patient, will yet succeed in overcoming the difficulties in many an unpromising case.

MEDICO-LEGAL ASPECTS OF SOME INJURIES OF THE SPINAL CORD.

Read before the Chicago Medico-Legal Society, October 6, 1888.

BY JAMES BURRY, M.D.,

SURGEON TO THE C. S. F. AND C. RY.; CONSULTING SURGEON TO ST JOSEPH'S HOSPITAL, JOLIET, ILL., ETC.,

— AND —

E. W. ANDREWS, M.D.,

PROFESSOR CLINICAL SURGERY, CHICAGO MEDICAL COLLEGE; SURGEON TO MERCY HOSPITAL, CHICAGO, ETC.

Within a period of five years English railway companies have paid in damages in cases of alleged injury to the spinal cord, the enormous sum of £2,200,000, or \$11,000,000. In our own city, the greatest railway center in the world, and in

other parts of our country, large sums have been paid as compensatory damages in similar cases. \$300,000 it is said were paid to the sufferers in the Chatsworth accident, and the largest individual damages were paid in settlement of cases of spinal injury. Specific instances of the enormous sums which have been awarded to this class of obscure injuries are:

Case of Waterman vs. the Chicago & Alton R. R.—The plaintiff claimed large damages for spinal concussion said to be produced in an accident. Dr. Clark Gapen and other experts testified that injury was the cause of the patient's symptoms, while Drs. Senn and Whiting testifying as experts for the defense agreed in stating that the patient had locomotor ataxia. A verdict of \$23,000 was awarded.

Case of Holland vs. the Chicago & Eastern R. R.—The plaintiff, an employé of another line, was injured in a collision and afterward reported for work apparently well. He was not given employment. Shortly after this it was claimed that symptoms of spinal concussion developed and permanent disability followed. Large damages were claimed and the plaintiff was awarded the sum of \$23,000.

Case of Rozenzweig vs. the Lake Shore & Michigan Southern R. R.—The plaintiff having been put off a train at a place not a regular station, was walking across the tracks, and either tripped over some object or was knocked down, he did not know which. Spinal injury of an obscure type was alleged and heavy damages awarded. The case after final appeal to the Supreme Court of the State, was settled by the road paying to the plaintiff \$48,500 with interest, or in all over \$50,000 compensation.

Case of Phillips vs. the London & Southwestern Rr.—The plaintiff, a physician, was disabled about two years by a railway injury to the spinal cord. It was proved that he had possessed a practice worth \$40,000 per annum, and a verdict of \$80,000 was given. Dr. Steele, who has met Dr. Phillips during the past summer, informs us that he is, except for a slight lameness, quite restored to health.

In examining the expert medical evidence in the above cases one cannot but see the over-shadowing influence of the theories laid down by Erichsen in his work on "Concussion of the Spine." A careful and comparative examination of these theories of Erichsen with those of later investigators in neuro-pathological fields may be of interest.*

Erichsen teaches, that there are two opposite and distinct conditions produced in the spinal cord by injuries. In one there are all the usual and visible effects of traumatism elsewhere—laceration of tissue, hæmorrhage into the spinal canal or substance of the cord and inflammation of the cord and membranes. In the other there

⁵ Arch. f. Klin. Chirurg.

are no definite structural changes, but only that condition which he describes under the term "anæmia of the cord," and which he himself admits can only be inferred and is not a well-proved pathological fact.

Cases of the first class, viz., those in which definite structural changes are produced, always give rise in his opinion to definite symptoms and are easily recognizable pathological states. In his ideas of the gross pathology we find nothing essentially different from the views of the older pathologists. Thus we find him describing the condition produced by myelitis as softening of the cord, notwithstanding the fact that modern investigation has shown that inflammation does not always produce softening, and that the latter may exist without myelitis. (Gowers.)

Grosser structural lesions are not the condition, however, which have given rise to conflicts of medical evidence. It is upon Erichsen's description of the second class of cases, viz., those in which there are no visible structural alterations, that the greatest and most numerous claims for compensation have been built up. It is well therefore, in view of the conflicts of opinion which have arisen, carefully to examine the evidence as to the existence of this second class of cases, described under the term "anæmia of the cord."

Accuracy in the use of scientific terms, may properly be demanded in a work which is so often quoted in medico-legal contentions. How much evidence is there then of the existence of any such pathological conditions as "anæmia of the cord?" Dana in his latest writings asserts: "Chronic spinal anæmia can hardly be placed in the category of distinct spinal affections." Gowers, in his work just from the press, embodying the results of original and exhaustive research says, in discussing anæmia and hyperæmia of the cord: "The condition of the vessels of the spinal cord after death affords no indication whatever of their state during life. . . . Local variation occurs only in the local hyperæmia which attends inflammation and the anæmia which results from pressure; hence the occurrence of variations in the state of the vessels of the cord and the effects that such variations may produce are matters of inference from symptoms observed during life, symptoms that are themselves open to various interpretations. Where the ground is barren of facts, theory is always luxuriant. Anæmia or congestion of the cord affords a ready explanation of symptoms, the cause of which is unknown, and it is scarcely surprising, therefore, that such an explanation has often been given. Some surprise may, however, reasonably be felt at the absolute confidence and precision of detail with which these states have been invoked as morbid processes, when the opinions expressed rest not upon one tittle of definite evidence. Positive assertions always receive some credence, however unwar-

ranted the assertions may be, and positions incapable of proof are also sometimes incapable of disproof. It would be futile and useless to attempt to refute in detail the various statements that have been made regarding anæmia and hyperæmia of the spinal cord. . . . We know nothing of it as an independent condition; nevertheless, volumes might be filled by the collected descriptions of the varieties and symptoms, descriptions in which the unrestricted play of "scientific" fancy has elaborated a symptomatology for the separate congestion of every part of the spinal cord." It is doubtful if any symptoms can be, with confidence, assigned to mechanical congestion.

In the face of these modern views, what weight shall be attached to the opinions on matters of obscure pathology of a writer who not himself a specialist in neurology, nor possessed of any of the recent methods of investigation, nevertheless lays down such positive dicta. Views which were published in 1866, twenty-two years ago, remain, according to his statement in the latest edition, "substantially unchanged" to-day. Within recent years the minute and gross pathology of the spinal cord have been almost entirely re-written. Intelligent discussion of the structural changes which occur in the cord in disease and injury are impossible without reference to the investigations of Charcôt, Brown-Séquard, Gowers and Bramwell. Yet, most of these investigations have been made since the publication of Erichsen's treatise and therefore find no place in his system of pathology. This would not be surprising, were it not also true, that Erichsen holds to substantially the same ideas in his latest writings. What weight should now attach to expert evidence based only upon inference from clinical experience, when diametrically opposite testimony rests on the firm basis of post-mortem and microscopic investigation?

That we may not appear in any particular to misrepresent this writer's opportunities for exact knowledge, we may quote his own words in his latest edition: "No instance (of post-mortem examination) has occurred to me in hospital, or in private practice, in which I could obtain one . . . The only case indeed on record with which I am acquainted, in which a *post-mortem* examination has been made, in a person who died from the remote effects of concussion of the spine, was published by Dr. Lockhart Clark," etc., etc., etc., in 1886.

What is surprising is not so much that these opportunities were wanting—for it is only of late years and in a few hospitals anything like systematic work has been in this line—but rather that on such a small basis of known fact so large a structure of inferential pathology has been built, and that it should be stated with the positiveness of well-proven facts and should have carried such

weight in the medical world. Even with the same method and from the same observed facts, we find no agreement among those who would dogmatize as the existence of lesions in preference to discovering them in the dead-house and with the microscope. Erichsen has collated a large number of cases from various sources to illustrate certain theories of spinal concussion. Page, on the other, pursuing the same clinical method, has drawn largely from the same sources and even from Erichsen's own published cases to support views of a nature directly opposite. Neither writer has utilized modern methods of study, and we are left with the impression that much of this discussion is but threshing old straw, so far as scientific results are concerned. If the conclusions of these older writers are in any measure weakened by being thus at variance, they certainly are still more discredited when it is found that they are at variance with modern ideas.

Nevertheless, the old, not modern views, still exert a deciding influence in many cases of alleged spinal injury which assume a medico-legal aspect, and many an expert has testified in court substantially to the ideas of a quarter of a century ago, in seeming ignorance of the revolution which cellular pathology has brought about in the last decade.

Erichsen is in accord with later writers in stating that when there have been actual structural changes in the cord, well-marked symptoms are developed. He loses sight, however, of the additional fact, that long continued functional disease produces structural change, when he advances his argument in behalf of "railway spine" and claims it is essentially a functional disorder and therefore not accompanied by the usual symptoms following structural change.

Many months, in the opinion of this writer, may intervene between the time of injury and the beginning of the symptoms of so-called spinal concussion. If, however, the two facts are connected, some functional or structural change must have been going on in the interval. If functional disorder cannot exist except transiently, it follows that the disorder must be, or become structural, or else cease to exist. But we have seen that structural disease produces definite symptoms and not vague and irregular phenomena. What becomes then of the theories of spinal concussion which, upon the assumed and wholly imaginary pathological state, known as "anæmia of the cord," build up a symptomatology equally vague and illusory? In this symptomatology have been included all the mental, psychological and cerebral symptoms which a person who has not met with an accident may suffer, as well as all the minor ills of each and every part of the body which could by any stretch of reasoning be traced to the nerve centers, and all are declared to have their origin in a condition of the cord which modern

pathology knows not, or recognizes only as transient.

If it be true that Erichsen's theories of pathology are undermined by the results of more modern investigators, what becomes of the vast superstructure of symptomatology which he has reared thereon? It is essential, if we would be scientific, that we refer only those symptoms to the spine which are known to be spinal. This is now very strongly insisted upon by writers too numerous to quote. No proven facts warrant the belief that mental and psychical disturbances, loss of memory, business inaptitude, depression of spirits and the like, have anything to do with the spinal cord. On the contrary these are truly cerebral symptoms to the best of our present knowledge, and, as such, can be understood and accounted for on plain pathological grounds. Serious they may be, but they are removed from the realm of the mysterious when we recognize their true origin and we can speak rationally of their prognosis and treatment.

But when these cerebral disturbances are referred to that vague state known as "spinal concussion," they seem to take on new terrors, and the patient sees in the diagnosis a dreadful portent of hopeless invalidism or gradual progressive decay. If once he has had Erichsen's picture impressed upon his imagination, he certainly will not lack for material out of which to build a gloomy prognosis. To all intents this writer lays down the opinion that any and every bodily ill may find its explanation in "anæmia of the cord" resulting from "spinal concussion." That this invites not only self-deception, but corrupt practices, we fear there can be no doubt, and such a state of affairs may well be a cause of alarm. Medical men have good reason to fear a condition of things which tends to discredit scientific medicine and the value of expert evidence. Lawyers have good cause to fear a state of affairs which may impose pseudo-scientific doctrine upon the courts in such a way that it cannot be sifted and analysed. Honest claimants are doubly interested in keeping false claims from being allowed to the prejudice of honest ones. Finally, courts themselves have most of all to fear a state of uncertainty in high expert authority, which will invite fraud and defeat the end for which courts of justice exist.

Spinal concussion, when used as Erichsen teaches, is a condition built up almost wholly of subjective symptoms. This renders malingering easy. To illustrate, a man who fears his back has been injured in an accident, consults a lawyer as to the liability of the corporation or individual for the occurrence of the accident. The lawyer—and there is a lawyer to every one hundred men in this city—sends the claimant to a physician—and there is a doctor to every one hundred men in this state—who goes over the ground very carefully with the claimant and asks him if he

suffers from such and such symptoms, and in order that there may be no mistake about it, gives the claimant a written statement of the symptoms usually occurring in well-marked cases of spinal concussion without structural lesion. The claimant, even if he be an honest man, after carefully questioning himself, discovers that he has become the possessor of an inaptitude for business, a mental disquietude, a pain in the back, etc., etc. If he be a dishonest man he studies his chart and has a stock of symptoms on hand when interrogated as to his condition, and in his business, it is "no trouble to show goods." We thus see that the way to imposition is made easy. Avenues of fraud are opened up, and capital, lawyers and courts are practically at the mercy of a clever malingerer. The writers of this paper wish to emphasize the importance of careful and not superficial investigation, and do not believe that the dogmatic precision of an old and inferential pathological which conflicts with modern pathological views, should give answer to the questions arising in alleged injury to the spinal cord.

REMARKS ON MEDICO-LEGAL ASPECTS OF SOME INJURIES OF THE SPINAL CORD.

Read before the Chicago Medical-Legal Society, Oct. 1888.

BY HENRY M. LYMAN, M.D.,
OF CHICAGO.

I have listened with a great deal of interest to the valuable paper of Drs. Burry and Andrews, and I must subscribe most heartily to the propositions advanced in it. It is, as the Doctor has well said, true, that the minds of the profession have for many years been too much under the influence of the dogmas laid down in Erichsen's work on "Railway Injuries." I am thoroughly satisfied that a great deal of injustice has been done and carried out through the agency of the courts upon the basis of opinions that have been formulated in accordance with that book, and I think it is really a very necessary thing to frequently give a word of caution like this to the profession that they avoid falling into the trap which is unwittingly opened before them by such a work. It has been well said that the pathology of the work is old and the inferences drawn from the cases are many of them strained, and yet it must be acknowledged that there is a sufficiency of truth in a good deal that is advanced in it to make the errors that accompany it doubly dangerous. If I were to speak of books in comparison with one another, I should say a book like Page's, while it may be open in many particulars to the charge made against Erichsen's work, of being old fashioned and representing somewhat bygone pathology, of the two it is far the superior work.

It is written in a much more judicial spirit and I think much more really and fully represents the advanced views of the profession in these matters than does Erichsen's work.

My own observation in cases of this kind, leads me to feel that a very large proportion of the cases which have been reported and presented in the courts as cases of spinal concussion are really nothing of the kind; they are cases in which, when there is any real lesion, where any real injury has been sustained, it has fallen more largely upon the brain than the cord. Many of the symptoms presented by these patients can be much more accurately described by supposing the brain is the organ that has suffered. It is in cases of this class that so many of the numerous and ill-defined symptoms following an injury, occur; patients who suffer with no systematized lesions, with nothing that can be referred to any disorganization proper of the spinal cord, no true paraplegia or hemiplegia; the lesions are those largely of an irregular distribution where the phenomena are largely mental, and possibly, in many cases, intellectual, and we must refer them chiefly to the brain rather than the spinal cord. It is true of a great many of these cases that the symptoms presented are of this character instead of being symptoms of paralysis either of sensation, motion or nutrition.

We have a large class of cases presenting themselves after these injuries to which the most convenient term we can apply is hysterical; hysterical conditions following injuries. These occur in males as well as in females. We perhaps have more right to expect the existence of hysteria in females who have suffered injury, but many cases of males who have suffered injuries are followed by hysteria, which can only be ascribed to disorders of the cerebrum. In regard to these so-called hysterical symptoms—how far are they to be allowed weight in judging of the liability of a railroad? For example, in the case of an injury that has been sustained, the courts will hold that it matters not what the form of the disorder is, so long as there is a disorder, for the disorder is the consequence of the injury that has been sustained, and the party inflicting the injury is liable for it. There is a certain amount of truth in that proposition; it but must be taken into consideration that disorders of this kind are most intensely liable to exaggeration as a consequence of the peculiar conditions which surround patients who have undergone the experience passed through by the victims of a railroad accident. The injuries are of a nature to disturb the mental functions of the individual, and the anxieties that grow up, partly through the agency of physicians, and partly through the uneasiness attendant upon law suits connected with the railroad company, or parties implicated in the accident, lead to disturbances of the mind to a great extent, and we

should take those things into consideration in our estimation of the probabilities of recovery.

It is a matter of common observation, that when patients have been injured in this way and manifest these mental and intellectual symptoms conjoined with a certain amount of vital innutrition and disorder, when the mental perturbation has been removed there is a great improvement in the symptoms; so that the settlement of a claim against a railroad company is followed by a rapid improvement in the condition of the patient. That is a fact which is often laid hold of by a certain class of physicians and surgeons and used as an argument against the genuineness of the sufferings experienced by the patient. They say it was a matter of imagination, of self-deception, and sometimes go so far as to claim a form of malingering by the patient. But if you reflect upon the relation which exists between the mind and body, it is easy to understand how a person who is in anxiety of mind will suffer, in an aggravated degree, bodily symptoms, and will improve again. It must be kept in mind that many of these patients are really permanently injured, though they have not received any injuries that are enduring from a surgical point of view. There have been no fractures, perhaps; no permanent strains or sprains or dislocations; no wounds anywhere, no depressions of the cranium, or anything of that kind. Many of these cases, therefore, when they have passed out of the immediate care of the surgeon are considered cured, and surgically speaking they are cured; but we must remember a case may be cured surgically and yet not cured medically, and, therefore, a certain class of patients must be recognized as never recovering fully from these injuries; they recover surgically and to a certain degree medically; but, as in a case of inflammation of the spinal cord, when a patient is suffering from myelitis we get a recovery to a certain degree, in the majority of cases, but rarely a complete recovery.

The patients get to walking about with more or less degree of comfort, but never recover the power of locomotion they once had; they have not the power of endurance they once had, and in every respect they are weaker and inferior in their condition to what they were before the injury was sustained. That is something that should be recognized and kept in mind, therefore, that the opinions of physicians and surgeons who are called to examine these cases for injury, should be guarded. I do not know that there are any class of cases in which it is more improper to give a positive prognosis, than in those of severe injury. The probabilities are in favor of partial recovery, that the recovery will be progressive; and yet in every instance the possibility exists that the recovery will be arrested short of complete restoration, and it is impossible, so far as my knowledge extends, to judge in any particu-

lar case whether it is going to be a case that is completely curable or whether it will come to a standstill before recovery has been completed. There is a class of cases in which the difficulty is principally mental, and those cases may recover completely, I think; and yet it is not possible for the physician to predict positively in those cases, at an early period, that they are going to be of that curable character. And yet where there is no palpable lesion, no evidence of disorganization of the brain or spinal cord; where the female sex is present, especially in a person of comparative youth, and where there is the possibility of complete change of life and occupation coming in to assist, the prospects of recovery are good.

I remember a case related by Dr. Wood, of Philadelphia, where a young woman had sustained an injury in a railroad accident. She had been examined by numerous physicians who had all given an unfavorable prognosis; not less than ten neurologists assured her she would never recover. That woman came under the care of Dr. Wood and he assured her there was nothing but hysteria the matter, and put her upon a course of treatment; and finally she engaged in a love match which terminated in marriage and she was completely cured. I think there is nothing so good as something to absorb the patient and turn the current of thought entirely from oneself and maladies, into another channel; it is the very best influence toward restoration of health to the mind; and in many of these cases it is a mental disorder that exists. I do not wish to take up the time of the Society, but would call attention to the fact that there is a class of people who are in such a state of mental instability that it needs only an excess or injury of some kind to start them upon a course of mental disorder which will have, we know not what termination. In patients of that class, injured by railroad disaster, followed by unfavorable opinions of men in high standing, and by long litigation, nothing is better calculated to set up a state of ill-health, the termination of which can never be predicted.

PROFESSOR HEINRICH VON BAMBERGER died at Vienna on Nov. 9 after an illness of several weeks' duration. He was born in 1822, near Prague. In 1850 he went to Vienna to work with Oppolzer, but went to Würzburg in 1854 as Professor of Clinical Medicine. Upon the death of Oppolzer he returned to Vienna, and in 1872 was appointed Director of the Medical Clinic in the Allgemeines Krankenhaus. Bamberger was an exceptionally gifted man. As Nothnagel recently said of him: "He thought as a *savant*, and practiced as an artist. Therein lies the secret of his fame as a physician, as diagnostician, and as clinical teacher. . . . The name of Bamberger, the clinician, links itself brilliantly to those of Skoda and Oppolzer."

MEDICAL PROGRESS.

THE MILK-CURDLING FERMENT OF THE STOMACH.—DR. E. G. JOHNSON has studied the action of the milk-curdling ferment of the stomach in the clinic of Professor Riegel of Giessen, and subsequently in the Sabbatsberg Hospital, Stockholm. Researches were made in 24 cases on the presence of the ferment and the pathological conditions relative to it. Fourteen of these patients suffered from hyperacidity, accompanied in four of them by moderate dilatation of the stomach. In one of these latter there was also hypersecretion of the gastric juice. One case had considerable dilatation of the stomach with hyperacidity and marked hypersecretion. In three cases the dilatation was insignificant, but there was hyperacidity, complicated in one case by slight, and in another by very great, hypersecretion; in the third case the hyperacidity was accompanied by chlorosis. Three other patients suffering from hyperacidity were also the subjects of gastric ulcer. Dr. Johnson also examined four cases of hyperacidity with neither dilatation nor hypersecretion, of whom three were chlorotic; a case of catarrhal jaundice, four cases of severe chronic dyspepsia, and five cases of carcinoma of the stomach. The contents of the stomach were removed while the patient was fasting, and also four or five hours after food had been given for the purpose of the observations. Dr. Johnson sums up his researches as follows: 1. The milk-curdling ferment is a constant product of the glandular secretion of the stomach, and it is met with at all periods of digestion except in cases of cancer of the stomach, in which it is never found. 2. The ferment was also found in the hypersecretions of the gastric juice of a fasting patient after his stomach had been washed out the previous evening. 3. Gastric juice which contains hydrochloric acid, and which when neutralized causes coagulation of milk, does not appear to be affected in its action by the greater or less amount of acid contained in it at first. 4. The milk-curdling ferment does not pass into the urine. 5. The ferment is easily destroyed by an excess of alkali, and it is probably on this account that it does not pass into the feces under normal conditions. 6. During fever the ferment appears to be absent from the stomach. 7. The ferment causes coagulation more slowly in boiled than in fresh milk. 8. During the coagulation of milk by the ferment the reaction remains neutral, and lactic acid is not met with after coagulation.—*The Lancet*, Nov. 17, 1888.

ALCOHOLISM.—DR. LEWIS D. MASON discusses, in the *Quarterly Journal of Inebriety*, the etiology of dipsomania and heredity of alcoholic inebriety. He has collated a large amount of testimony bearing on this subject; and from this, and from

his own experience, which has been very large, he draws the following conclusions: first, alcoholism in parents produces a degenerate nervous system in their children, and subjects them to all forms of neuroses, epilepsy, chorea, paralysis, mental degeneracy, from slight enfeeblement to complete idiocy and insanity; second, alcoholism in parents produces a form of inebriety in their children known as dipsomania, which in the large majority of cases is inherited in the same manner that other diseases are inherited, and we can with propriety and correctness use the term "alcoholic or inebriate diathesis" in the same sense that we use the term "tubercular," or other terms indicating special tendencies to other inheritable diseases.

TREATMENT OF PNEUMONIA BY DIGITALIS.—M. PETRESCO has treated a large number of cases of acute pneumonia with great success by the administration of four grams of digitalis leaves in infusion every half-hour, by mouth. The infusion is prepared with 4 grams of digitalis leaves to 200 grams of water and 40 grams of syrup. The disease is generally checked in three days. The fever and all the physical phenomena, local as well as general, disappear rapidly. In spite of the large doses he has never seen poisonous effects, tolerance having been uncontestedly proved by 577 observations. By this treatment it is claimed that the mortality of pneumonia has been reduced to 1.22 per cent.—*Leyon Medical*, October, 1888.

TREATMENT OF INFANTILE DIARRHOEA.—ZINNIS recommends for the diarrhoeas of childhood, particularly the cases characterized by green evacuations containing undigested casein, the withdrawal of all starchy food, and the following mixture:

Aque. fenic	75 parts.
Liquor. calcis	6 "
Bismuth. subnit	3 "
Syr. aurant. flor	15 "

mg.

S. Give a dessert-spoonful every 2 hours.

—*Deutsche Med. Wochenschrift*, Sept. 6, 1888.

USES OF CREOLIN.—LICHTWITZ thus sums up the uses of creolin: It is an antiseptic, a disinfectant, a hæmostatic, and non-poisonous in doses as large as 120 grains. In gram doses in capsules it is useful against *tania solium* and *oxyuris vermicularis*. Its action is excellent in parasitic skin diseases, and in eczema. Given internally it is a valuable antifermentative. It may be used by inhalation in laryngeal and tracheal troubles, and the powder may be applied locally. Creolin powder has a good effect in some cases of keratitis.—*Nouveaux Remèdes*, October, 1888.

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 68 WABASH AVE.,
CHICAGO, ILLINOIS.

All members of the Association should send their Annual Dues to the *Treasurer*, Richard J. Dunglison, M.D., Lock Box 1274, Philadelphia, Pa.

LONDON OFFICE, 57 AND 59 LUDGATE HILL.

SATURDAY, DECEMBER 15, 1888.

THE AMERICAN ACADEMY OF MEDICINE, AND
MEDICAL EDUCATION.

In reading the abstract of the proceedings and papers presented at the recent annual meeting of the Academy, in THE JOURNAL of the 8th inst., we noticed some statements calculated to convey impressions not in strict accordance with the facts of history. It is natural and commendable for members of any legitimate society to magnify the importance and influence of the society to which they belong, provided they do not detract from the labors of others or use such expressions as lead to erroneous inferences. The abstract to which we have alluded represents the writer of "A Few Words Concerning the Academy" as making the following statement: "The Academy was organized in 1876, at a time when the standard of medical education was at its *lowest point*. Medical institutions were numerous and their doors thrown open to all, irrespective of qualifications. . . . It was at this period that the Academy began to explore these novel methods of manufacturing medical practitioners."

If the writer of these statements will turn to the "Reports on a Uniform Standard of Medical College Requirements, and on Medical Education," contained in the first volume of the Transactions of the American Medical Association, 1847-8, he will find that the standard of medical college education at that time, demanded no preliminary education, and attendance on only two

courses of college instruction averaging sixteen weeks each, the minimum being thirteen and the maximum eighteen weeks. Less than half of the colleges required attendance on any clinical instruction, and only one-third made dissections obligatory upon the student. This being the standard of medical education in 1846, if it continued to deteriorate during the succeeding thirty years and reached its "*lowest point*" in 1876, it must have required a microscope to find where it was at that date, when the Academy came into existence. But what are the facts? At almost every succeeding annual meeting of the American Medical Association an able report on the subject of medical education was made and discussed until 1866, when it culminated in the recommendation that a convention of delegates from the medical colleges alone be held for the purpose of maturing and adopting a uniform plan and standard of medical education. The convention was held in Cincinnati, May, 1867, and was presided over by the eminent Alfred Stillé, Professor of Practice of Medicine in the University of Pennsylvania. During three days of earnest and harmonious deliberation, a full graded three years' course of medical college instruction, including a fair standard of preliminary education before commencing medical study, practical anatomy, and hospital clinical instruction was adopted, and laid before the faculties of all the colleges in this country. A second convention was held in May, 1870, the whole subject again discussed and the same liberal graded plan was re-adopted, and the same received the unanimous sanction of the American Medical Association. In the meantime the Chicago Medical College had been established in 1859, seventeen years before the organization of the American Academy of Medicine, with a three year graded system and six months college term, and in 1871, five years before, the Medical School of Harvard University adopted the same, to be soon followed by the Medical Department of the Syracuse University, and the old University of Pennsylvania. The colleges generally had increased the length of their college terms and the number of their professorships. Indeed, it was the steady progressive development of professional opinion by the reports and discussions in the American Medical Association, the college conventions alluded to, and the State Medical Societies, during the thirty years following 1846,

that made it possible to organize and maintain the American Academy of Medicine in 1876, and the Illinois and many other State Boards of Health since.

THE MEDICAL COLLEGE OF VIRGINIA.

In another department of this week's issue of *THE JOURNAL*, will be found a letter on this subject from DR. J. S. DORSEY CULLEN, Dean of the Faculty of the Medical College of Virginia. The first paragraph of the letter is of such nature that we would be fully justified in refusing to publish it. The English language is broad and flexible enough to permit one to be severe and critical without being offensive, or violating its rules of orthography and syntax.

As every one must know, individuality is dropped in editorial writing. It is a well-settled principle that the editor of a journal is responsible for unsigned articles. While the editor may not write all that appears in his editorial pages, whatever appears therein has his full consent. An editor cannot allow personal prejudices to direct or influence articles for which he is responsible. Dr. Cullen's position of claiming to respect *THE JOURNAL*, but at the same time caring nothing for an opinion expressed in its editorial columns, and opening his letter with an offensive paragraph, is, therefore, as paradoxical as his first sentence is ungrammatical.

Whether or not the statements made in *THE JOURNAL*, concerning the Medical College of Virginia are "flagrantly at variance with the truth," we leave our readers to judge from the facts already and to be presented. Dr. Cullen states three charges made against the College *by its enemies*. *THE JOURNAL* is not an enemy of this College, and does not feel itself called upon to take part in a personal controversy between the College and its enemies. It does feel called upon to expose any medical college that graduates incompetent men; it has that right, and will do so whenever it has the facts to go upon.

Dr. Cullen seems to have misunderstood the charges made by *THE JOURNAL* against his College. Briefly they were as follows: 1. That it has, with some other medical colleges, done bad work by graduating incompetent men. 2. That it was, at least from January, 1888, to the time the editorial articles appeared in *THE JOURNAL*,

opposed to the Medical Examining Board of Virginia. 3. That in January, 1888, the bad work of the College was practically admitted by the fact that the students of the College, supported unofficially by members of the Faculty, went before a committee of the Virginia Legislature and asked that the students of the Medical College of Virginia be exempt from the State Examinations. We did not say that the Faculty of the College was opposed to the *establishment* of a State Medical Examining Board; we knew the contrary, as shown in *THE JOURNAL* of Sept. 8, p. 346. In the same issue we stated the so-called reasons given by the students of the College to the Legislature why their graduates of the College should be exempt from State examinations. Some members of the Faculty must certainly have seen the preposterous document of the students; and that the students were allowed to stultify themselves by it without protest from the Faculty is at least presumptive evidence that the Faculty considered it a proper article to emanate from their College. The members of the Faculty should have considered it a duty to say to the Legislative Committee that they could not approve of the memorial presented by the students.

The facts already presented in *THE JOURNAL*, including the table in Dr. Cullen's letter, already published in our issue of Nov. 24, p. 746, are proof enough that the Medical College of Virginia has not done good work since January, 1885. The table shows that some other colleges have done worse work; but it is no excuse for grand larceny that some one has committed murder. Dr. Cullen is quite right in saying that the Medical College of Virginia "had the smallest number of graduates rejected of any college whose number of applicants were (was?) equal to it (?)," seeing that no other college had an equal number of applicants by 23. Dr. Cullen finds that about 7 per cent. of the graduates from the Medical College of Virginia have been rejected by the Virginia Board. We believe that 8 is not "about 7 per cent." of 57, but 14.03 per cent. We did not find it necessary to establish the bad work of this College by comparing its work with that of other colleges; 14.03 per cent. of rejected applicants before the State Board is quite enough evidence of bad work.

If Dr. Cullen wishes to know why more was said of the Medical College of Virginia, in our

editorial articles, than of other colleges doing as bad or worse work, we may say that it was because the Faculty officially endorsed the establishment of the State Board of Examiners, and afterwards individually opposed the Board before the Legislature; because of the action of the students of that College in petitioning the Legislature of Virginia to exempt its graduates from the State examinations, and their reasons therefor; because the Faculty did not protest against this petition, and because of the statements made to the Legislative Committee by members of the College Faculty. The action of the students was substantially, though unofficially, it is said, endorsed by the members of the Faculty (except Drs. John N. Upshur and Geo. Ben. Johnston). If Dr. Cullen does not remember what the members of the Faculty said before the Legislative Committee, we can refresh his memory by publishing their statements. In regard to the misstatements refuted by Dr. Cullen at Norfolk, we can only say that none have been made in *THE JOURNAL*; and as to the statements that we have made, they have been refuted neither at the Norfolk meeting nor in the letter from Dr. Cullen in this issue.

We noted with pleasure the position taken by Dr. Cullen at the Norfolk meeting of the Medical Society of Virginia in regard to the State Examining Board. Inasmuch as he represents the Faculty of his College, until there is evidence to the contrary we shall accept his action as a promise that the Medical College of Virginia has entered upon an era of better work.

THE DIETETIC USE OF SACCHARIN.

In a recent number of the *Lancet* Drs. THOMAS STEVENSON and L. C. WOOLDRIDGE record some experiments made to determine whether saccharin is poisonous or not when given in excessive quantities; and if it is not poisonous under these or other conditions, whether its use in moderation interferes with the digestive processes, so as to render it advisable to forbid its use as a substitute for sugar. Saccharin is not a food in any sense; but it is recognized that there are many circumstances under which it is necessary to have a sweetening agent to take the place of sugar. As to the non-toxic nature of saccharin the experimenters have no doubt, since their experiments confirm those of reliable investigators on the Con-

tinent. Saccharin has decided antiseptic properties, and in sufficient quantities is capable of stopping the action of organized ferments. As regards its extracorporeal action on the soluble ferments, as regards the peptic digestion of fibrin 0.1 per cent. of saccharin has no retarding influence, while 0.25 per cent. slows the process decidedly, and 1 per cent. greatly retards it: 0.1 per cent. of saccharin is equivalent to 30 per cent. of sugar, which may be said to be a dietetic impossibility. The diastasic solution of starch is not hindered by 2 per cent. of saccharin. The addition of saccharin to urine hinders ammoniacal fermentation—as does ingestion of saccharin.

As regards the intracorporeal action of saccharin, it was found that a gram of the substance, equal to more than eight ounces of sugar, did not interfere in the least with the gastric digestion of the dog. The article used in the experiments was "soluble saccharin," equal to about nine-tenths its weight of pure saccharin. It is as soluble in water as table salt, and when properly diluted is scarcely to be distinguished from cane sugar. Drs. Stevenson and Wooldridge conclude that (1) saccharin is quite innocuous when taken in quantities largely exceeding what would be taken in an ordinary dietary; (2) it does not interfere with nor impede the digestive processes when taken in any practicable quantity; (3) it may be taken during an extended period without interfering with the digestive and other bodily functions. There is, then, no reason to think that its continual use may be in any way harmful.

EDITORIAL NOTES.

AN ARMY MEDICAL BOARD will be in session in New York City, N. Y., from May 1 to 31, 1889, for the examination of candidates for appointment in the Medical Corps of the United States Army, to fill existing vacancies. Persons desiring to present themselves for examination by the Board will make application for the necessary invitation to the Secretary of War, before April 1, 1889, stating the place of birth, place and State of permanent residence, and enclosing certificates based on personal knowledge from at least two persons of repute, as to American citizenship, character and moral habits. Testimonials as to professional standing, from Professors of the Medical College from which the

applicant graduated, and of service in hospital from the authorities thereof, are also desirable. The candidate must be between 21 and 28 years of age, and a graduate from a *Regular Medical College*, evidence of which, his Diploma, must be submitted to the board. Further information regarding the examinations and their nature may be obtained by addressing the Surgeon-General, U. S. Army, Washington, D. C.

ISOLATING "LUMP-JAW" CATTLE.—The Secretary of the State Board of Live Stock Commissioners reports that the Agent of the Board at the Union Stock Yards, Chicago, has, since the 15th of October, when he was placed there, isolated 148 cattle diseased with lump-jaw, and all but one of these have been slaughtered by the owners without cost to the State, thus preventing their going into the country to again spread disease. The action of the Yard Company in ordering the carcasses tanked has prevented the placing upon the market of diseased meat, which is likely to convey the disease to human beings. The Stock Yard officials and the commission men generally are co-operating heartily with the State Board in preventing the spread of the disease by absolutely refusing to handle any animal affected with the disease. The Board of Live Stock Commissioners has placed an agent at the National Stock Yards at St. Louis to inspect and isolate diseased cattle.

A NEW URINAL has been invented by a German firm. The long bag, which hitherto was hanging in an uncomfortable manner the whole length of the leg, is done away with, and its place taken by a bag attached to the waist and extending horizontally, the urine being kept at the bottom of the bag and spreading over its entire width, instead of accumulating at one point. Moreover, a pump and sucking apparatus is connected with the urinal for the purpose of making the reservoir air-tight and allowing the urine to flow very quickly by means of a valve into the lower part. The discharge is effected in a comfortable, very clean, noiseless and non-conspicuous manner, the emptying hose being mechanically opened, when the fluid runs away to the last drop.

ABNORMALITY OF THE AORTIC ARCH.—At the meeting of the Anatomical Society of Great Britain and Ireland on Nov. 7th, Mr. Gordon

Brodie related a case of abnormality of the aortic arch, in which the innominate arteries (?) were absent, being replaced by a short, thick trunk, which gave off two branches ascending on either side of the trachea to the place of the common carotids, that on the right giving off one corresponding to the vertebrae. Next in order from the arch was the left vertebral, which entered the foramen in the transverse process of the fifth cervical, and gave a branch to the thyroid. Another branch arose from the first part of the subclavian on the left side. The right subclavian arose as a fourth branch from the arch, and passed behind the cesophagus and trachea.

THE PROFESSION IN NEW MEXICO.—The Territorial Board of Medical Examiners of New Mexico made its report to the Governor on Nov. 29. There are 1,291 persons practicing medicine in the Territory. Of these 834 are regulars, 151 homoeopathic, 44 eclectic, and 264 non-graduates entitled to certificates owing to length of practice in the Territory. The Board revoked two licenses during the year, one for unprofessional and immoral conduct, and the other for passing a forged diploma and obtaining a license to practice. Eight have been obliged to leave the Territory to avoid prosecution under the act.

FALSE CERTIFICATE OF DEATH.—A physician in St. Paul, Minn., recently gave a certificate of death to the city health department, in which "sore throat" was given as the cause of death. The Health Officer, Dr. Kilvington, refused to accept it, and the physician then substituted "scarlet fever" for sore throat. The case should receive, and doubtless will have, full investigation. This kind of evasion of the law is both criminal and contemptible, and richly deserves punishment. Other cases of failure to report contagious and infectious diseases, are reported from St. Paul and Minneapolis.

INTUBATION OF THE LARYNX.—Dr. F. E. Waxham reports fifteen cases of intubation recently coming under his care, with ten recoveries, or 66 per cent. Out of a total of 173 cases there have been fifty-three recoveries, or 30 per cent., and of his last fifty cases there have been twenty-two recoveries, or 44 per cent.

THE SOUTHERN SURGICAL AND GYNECOLOGICAL ASSOCIATION met in Birmingham on December 4, with a large number in attendance.

SPECIAL ARTICLES.

HISTORY OF THE SEAL OF THE NINTH
INTERNATIONAL MEDICAL CON-
GRESS AND OF THE COMMEM-
ORATIVE MEDAL OF THE
CONGRESS.

As it may, at some time, be of interest to know the origin and history of the seal of the International Medical Congress of 1887, and also of the medal struck to commemorate the Congress, it is essential to collect the data now, and put the facts on record. This can be done most accurately by publishing the letter of Dr. J. M. Toner, written at the time to Prof. Henry H. Smith upon the subject. This letter, with the addendum, is supplied at our request, and furnishes a complete history of the matter. To make the history more complete, we append correct cuts of the two sides of the medal.

WASHINGTON, D. C., April 20, 1886.
PROF. HENRY H. SMITH, M.D.,

*Chairman Executive Committee of the Ninth
International Medical Congress:*

Dear Doctor:—Your letter requesting me to prepare a design for a suitable seal to be used on the official papers and publications of the Ninth International Medical Congress which is to meet at Washington, D. C., September 5, 1887, has been received. In addition to the seal, I fully agree with you in the sentiment that the occasion of the assemblage of representative medical men from all the civilized nations of the earth, gathered at the Capital of the United States, will be so notable an event as to deserve to be commemorated by a suitable medal. Since the receipt of your letter I have given such thought to the subject as I could, and have now the honor to submit for your consideration the enclosed drawings as a design for one side of a medal, and I propose that the same figures be engraved and used as the seal to be attached to official documents by the officers of the Congress. For the reverse of the medal I suggest that a figure of the head of Washington be adopted. A most excellent specimen of portraiture in medallion art is that of the head of this, the greatest man the world has produced, modeled from the Houdon plaster cast which was taken of him during life and engraved at the United States Mint in Philadelphia. This die or model can, I have no doubt, be obtained for your purpose. Washington's bust will properly symbolize the New World and our progress in civil government, as well as the arts and sciences in our country.

If, however, the bust of Washington does not seem to your committee as appropriate, then I propose that the symbolic figure of Europe and America, a rough sketch of which I enclose, be substituted. The group of figures on the medal

is intended to symbolize medicine. Æsculapius, the inventor of the art, is here represented as of noble and venerable form, draped in classic costume, seated, holding his staff entwined by a serpent, and attentively examining a sick child, which a mother seated on a low stool holds upon her lap. Two men are represented as standing soliciting the services of the physician, one with a staff and a bandaged head, the other supporting himself upon a crutch. The only accessory to the figures evoked by the artist is the Roman altar which is placed partly behind the chair of Æsculapius, and around which twines a serpent in the act of depositing a medicinal plant in a cup upon the altar. To typify medicine the classic figure of Æsculapius, which tradition and the arts have brought down to our time, has been accepted. The serpent and the other emblems which usually accompany his portrait are of classic origin and will be readily understood by the student of medicine, so that it is scarcely necessary to describe them, and yet a brief reference to their meaning as given by the ancients may be pardonable. It is known to scholars that Æsculapius, the god of medicine, was claimed to have been of divine origin—the offspring of Apollo and Coronis. The mother, concealing her pregnancy, withdrew to the forest in the neighborhood of Epidauris, and there brought forth a son and left him exposed on the mountain. The child was preserved by a stray goat, which nourished him with its milk, while the goat-herd's dog guarded him from injury. A shepherd watching his flock discovered the child, but was alarmed at seeing the infant surrounded by a resplendent halo of light, and fled, proclaiming that he had found a divine being. The infant was taken by Trigona, the wife of the goat-herd, and carefully reared until he reached an age to profit by the teachings of the famous Centaur, Chiron, under whose instruction Æsculapius attained wonderful proficiency as a physician. His great knowledge of the healing virtues of plants and other substances, and his skill in curing diseases and in the treatment of wounds, at length elevated him in the esteem of the age to the dignity of the inventor and god of medicine. The worship of Æsculapius was first established at Epidauris, and afterwards spread to and throughout Greece. In the beginning he was adored under the form of a serpent, though subsequently many statues were erected in the human form to his honor. The serpent is the symbol of renovation and eternity everywhere in classic sculpture, and graphic representations accompany the god of medicine. It is also the accepted symbol of health and life, and in one or another position is represented in all the statues of the god, and usually twining around his staff. One of the traditions as to the origin of this association of the serpent with the god of medicine is the following: While Æsculapius

was in the house of Glaucus, whom he was engaged to cure, and while standing with his staff in his hand absorbed in thought, a serpent came and twined around it, which he killed. Shortly after another serpent came, carrying in its mouth an herb, by the touch of which it recalled to life the one that had been killed. Æsculapius, observing the restoration of the dead serpent to life, took the same plant and used it with like effect in restoring health and life to men. This power, however, offended Pluto, because it diminished the number of the dead. Zeus therefore killed Æsculapius with a flash of lightning but, at the request of Apollo, he was placed among the stars.

Æsculapius is frequently represented standing, but a few classical groups exist which show him seated; one on a throne with his daughter Hygieia, the goddess of health, feeding a serpent, and Telesphorres, one of the minor gods who presided

once the sympathy of the beholder. The two men of good figure present evidences of requiring the skill of the physician, and add to the effectiveness of the group. The Roman altar with the serpent depositing a medicinal plant in the cup is classical in its origin and assists to complete the symbol of the origin of medicine.

Should your committee deem it wise to arrange for a medal I trust you will have it executed in the best style known to the art, and that it be left optional with the members to subscribe for it or not as they may elect. The taking of the medal of the Congress of 1881 in London was entirely voluntary. Its cost was five dollars. The one proposed for the Ninth Congress will cost the same; this amount to be paid at the time of registering. The medal to be delivered to subscribers as soon as it can be made.

The London medal had on one side the same

over convalescence, dressed in a monk's cloak and hood, standing by her. As accessories, artists have availed themselves of the figures of the goat and the dog which nourished and protected the infant god, and also of the cock which was frequently sacrificed to Æsculapius. But none of these have been introduced here. The head of Æsculapius, as represented in the best antique statues, much resembles that of Apollo, the features regular and of benevolent expression, the hair trained to ascend from a massive brow, parting in the middle and then falling down over the temples in a profusion of curls like the mane of a lion, and wearing a full though short and curling beard. The effect obtained by the artist in this group is pleasing. The pose and figure of Æsculapius is good, and his seated attitude gives him the air of earnest benevolence in the exercise of his humane office. The infant as presented by its mother enlists at

symbolical figure which appears on the seal of that Congress, and on the reverse side the bust of the Queen.

I would further suggest that you would submit the drawing for the medal to Mr. Barber, designer and engraver in the United States Mint in Philadelphia, and make inquiry of him as to size, cost, and the use of the model of the head of General Washington which I have referred to. He could give your committee at once an approximate estimate of cost, and thus enable you to come to a speedy conclusion of the matter.

Hoping to have the pleasure of greeting you and many old friends at the meeting of the American Medical Association in St. Louis in May, all full of wisdom and fortitude to work to the end of making the Ninth International Medical Congress a grand success, I remain, Yours very truly
J. M. TONER.

ADDENDUM, SUPPLIED BY REQUEST.

The design for the medal submitted as described in the foregoing letter was adopted by the Executive Committee as the seal of the Congress, yet they did not feel warranted in assuming the financial risk involved, and left the whole project of the medal to the registrar. The propriety of having a suitable medal engraved to commemorate the occasion seemed to be beyond question, and to justify the placing of a special notice regarding a commemorative medal at the bottom of the registration blank used by applicants for membership. This form to be filled up or not as members might choose to become subscribers. This view of obtaining the sense of the members of the Congress on the matter was approved by the Secretary-General, Dr. J. B. Hamilton, and that course adopted. The notice promised that a medal equal to that of the Congress at London would be ordered if a sufficient number were subscribed for at five dollars apiece to cover the expense, but if the medal was not ordered the money would be returned to the subscribers. A sufficient sum was raised to engage the services of Charles E. Barber, an eminent engraver and medallist employed in the United States Mint at Philadelphia, to re-draw the group of figures submitted and to place the following inscriptions in raised letters upon the face of the medal. The figures have been fully described in the letter to Dr. Smith. The inscription in a straight line beneath the group symbolizing medicine is, "*Washington, 1887*;" above and encircling the group, reading from left to right, "*International Medical Congress*;" beneath and completing the circle, reading from left to right, "*N. S. Davis, Pres. J. B. Hamilton, Sec.-Gen. E. S. F. Arnold, Treas. J. M. Toner, Reg.*" The reverse side of the medal contains a noble bust of Washington, and in a circular line above the head the inscription, "*United States of America*;" beneath in a circular line, "*Founder of the Republic*." The artist has been eminently successful in producing a beautiful specimen of medallie art, which we hope in a degree appropriately commemorates the Ninth International Medical Congress, and will at the same time be an acceptable souvenir of the occasion.

J. M. T.

CASES OF SUDDEN DEATH IN NURSING INFANTS.¹BY PROF. PAUL GRAWITZ,
OF GREIFSWALD

[Translated for the author by S. N. NELSON, M.D.]

The object of this communication is to call attention to a group of cases of death in nursing infants, which are of interest, because healthy

children died with the symptoms of suffocation without any preliminary evidences of disease. I have observed two such cases which throw some light concerning the cause of death. According to my idea, a greatly enlarged thymus gland is the real explanation of the sudden asphyxia in both cases.

The first case occurred about four years ago in Berlin. A child about 8 months of age was entrusted to the care of a servant girl. One morning this child, which hitherto had been entirely healthy, was found dead in bed. The feather coverlid, with which the little one was covered, seemed to be drawn somewhat high up over the mouth of the child. On account of these circumstances the attending servant girl was accused by the parents, and criminal proceedings were commenced against her for her carelessness. In consequence of this a judicial autopsy on the body was ordered, which I had the opportunity of conducting in conjunction with Professor Liman.

The little body was well developed and well nourished, and no traces of external injury could be found anywhere. Within the skull there was nothing abnormal. On opening the pleural cavity there presented a thymus gland of unusually large size, which covered over the greater part of the pericardium like a flat tumor, and which extended on both sides somewhat high up in the neck toward the thyroid gland. The gland had a lobulated structure and its surface was of a bright red color, studded everywhere with little punctiform hæmorrhages. On section similar little petechiæ could also be recognized in the interlobular tissue. In the pericardium, and also occasionally in the pleura, there were likewise found little extravasations. The heart was of normal appearance, the lungs were crepitant and entirely normal, and there were no foreign contents in the large or small bronchi. There were no changes worth mentioning in the organs of the abdominal cavity.

The preliminary opinions of both operators were that the child had died of suffocation. The proximate circumstances under which death followed we left undecided.

In the oral proceedings which followed it was established that the coverlet had not encumbered the face of the child to any unusual degree, and then it became necessary for both of us experts to explain more clearly the cause of the suffocation. In this respect our opinions differed; for while Professor Liman attached no special importance to the relations of the thymus gland, I believed that this was the cause, although I had had no special experience in similar cases. Therefore I gave this to be my opinion before the judges, and insisted that I was obliged to attach much importance to the very abnormal size of the gland, since its anatomical position² must have produced ex-

¹ A discourse delivered before the Stralsund Medical Society.² Deutschen Med. Woch., 1888, No. 22.³ In the skeleton of a child 8 months old, I find the distance

cessive pressure on the larger bronchi and the vessels lying behind it, and on this account it was not necessary to ascribe the death of the child to a crime.

The judges acquitted the accused servant; but they expressly declared that the judgment was given from lack of positive proof independent of the opinions of the experts.

Since that time until the present I have never met a case in which I could ascribe the death of the child to the thymus gland, although I have always had it in mind. I have just met a second case which in clearness exceeds the first in many respects.

§1 The daughter of Mr. J., in Greifswald, was a strong, well-nourished and lively child, 6 months old, who had never suffered from cough or any other illness. On the 20th of April of this year the parents of this little child were rejoicing. The father held it in his arms and was playing with it in the presence of some relatives. Suddenly the child was seized with difficulty of breathing, the face became livid, the fists clenched, and in a few minutes the child was dead. One of those present, an experienced nurse, immediately attempted to restore the child by artificial respiration, but it was in vain. The death certificate was made dependent upon the result of the autopsy, which I performed on the 21st of April.

Report of the Autopsy: The body of the child showed externally no traces at all of any injury. The skin of the face, on the body, abdomen and arms is white; on the back and legs livid. The subcutaneous fat is extremely thick. On the thorax can be felt a plain rosary of rickets. The thorax is broad, the abdomen somewhat swollen. The muscles are in rigor mortis.

On opening the abdominal cavity the small intestines filled with gas press forward, the serous covering is grayish white, delicate, and in several places the light rose colored Peyer's patches show through. In the abdominal cavity there are no foreign contents. The diaphragm on both sides in the mammillary line is at the lower border of the fourth rib. *Under the sternum lies a thymus gland of unusual size.* It covers the greater part of the pericardium with two lobes held together in the median line by connective tissue. It forms a thick cap over the heart with the concavity inwards.

Upwards the left lobe becomes gradually narrowed, but the right one, interrupted by a constriction, proceeds as a long process, which ends tapering. The greatest length from this process to the base of the thymus is 7.5 cm., and the greatest breadth over the pericardium 6 cm., the thickness (about 1.5 cm.) is difficult to determine, since at the level of the division of the bronchi, a

somewhat thick accessory lobe projects from the left lobe and is separated from the chief lobe by a constriction; but it partially overlaps it and thus adds to the thickness. *Diameter from before backwards on a level just below the manubrium, is less than 1.8 cm.; the color is gray-rose, sprinkled with numerous superficial petechiæ of fresh red color; the consistency is somewhat hard; the heart is relatively large and strong.* In the visceral pericardium are numerous red extravasations of the size of the head of a pin. The muscles of the heart, the valves, and the foramen ovale are normal. In the cavity is considerable fluid blood, as also in the vena cava and in the veins of the neck.

The organs in the neck are removed in connection with the lungs. The mouth and pharynx are empty and so is the opening of the larynx, the trachea and the large bronchi. The epiglottis shows an exquisite lateral compression (asphyxiated position of Virchow). Its mucous membrane, like that of the pharynx, is congested. The interior of the larynx and the upper part of the trachea are of a considerably brighter red color, and a more marked injection commences just over the bifurcation, which corresponds to the narrowest spot between the sternum and the vertebral column. In the large and small bronchi there is some clear reddish froth, the lungs are considerably collapsed, everywhere containing air, bright red, and here and there on the surface are little blebs of interstitial emphysema. The œsophagus is empty. In the stomach are some milky contents and a considerable accumulation of gas. The mucous membrane is of a pale grayish white. In the intestines likewise, is thin chyme and gas, and the mucous membrane is of a delicate clear gray color with somewhat marked rose-colored, but not swollen, Peyer's patches. The spleen is large and full of blood with very prominent little follicles. The liver is full of blood but otherwise quite normal as are also the kidneys. The mesenteric glands are somewhat enlarged, grayish red, and the chyle vessels are filled with white contents.

Diagnosis.—Death from suffocation on account of hyperplasia of the thymus gland.

Conclusions.—Both of the above-mentioned cases have in common that there was no real illness like an asthma or any similar disease, but that the nurslings had died absolutely healthy. *In both of them the autopsy had given as the cause of death the report usually reached in a case of death from suffocation, and in both only the enlarged thymus was anatomically found as an explanation for the suffocation.* The minute hæmorrhages which were present in large numbers in both thymus glands exist in cases of suffocation and correspond to punctiform hæmorrhages in the pericardium and in the pleura.

Since, however, in the first case the suspicion cannot be absolutely removed that the servant had

from the manubrium of the sternum to the vertebral column to be 2 centimetres, therefore this is the dangerous point at which an enlargement of the thymus of 1 or 1.5 centimetres in thickness must essentially narrow the space.

covered the child too much, and thus had aided in causing death, yet in the second case the child was awake when the difficulty in breathing occurred, the parents and several persons were present, and every unnatural influence was thoroughly excluded. So far the facts go.

If it is now asked, whether nothing definite is known about cases of death of this sort, it must be assumed that the judicial physicians in general attach no importance to hyperplasia of the thymus, since nothing is found about it, at least in the mortality statistics of the well-known text-books of Liman and von Hofmann. On the other hand, quite a lively debate is carried on concerning the importance of the thymus in the 40th or 50th years. In Alexander Friedleben's book, "The Physiology of the Thymus Gland in Health and Disease, etc., 1858," is found a very fertile research into the literature of old authors and in a supplement, page 248, is "a case of sudden death in the first act of laryngismus," with which both of my cases correspond in a striking manner. Nevertheless it is evidently this very work which is chiefly to blame for the later neglect of these cases, since Friedleben, after a long criticism, came to the conclusion that we have overestimated its importance even in such cases of sudden death. Evidently, then, the frequency of really enlarged thymus glands was overestimated and a special disease was established, called *asthma thymicum*, which should always have such a hyperplasia as a foundation. Now it naturally happened that cases of difficult breathing in children were infinitely more frequently observed than enlarged thymus glands were found at the autopsies, so that all sorts of diseases of the lungs and air passages were classified under the great head of *asthma thymicum*.

On the other hand cases came under observation in which, as in both of those mentioned above, no sort of symptoms of disease existed and in which, nevertheless, a thymus gland was found, which occasionally was still greater than those belonging to nurslings that had died of *asthma thymicum*. What was more natural than that Friedleben came to the conclusion that these relations of size were to be considered normal, since the glands had caused no difficulty previous to the first fatal attack, and that he finally denied not only the *asthma thymicum*, but also the possibility of a dangerous hyperplasia of the gland.

I am not exactly in the condition now, with only my two cases, to contradict the authority of Friedleben, which is given on an astonishing number of individual experiences, but I believe that I can draw two conclusions which render doubtful the value of his negative standpoint. In the first place, Friedleben deals just as radically with tumors of the thymus as with hyperplasia of the thymus. The opinion of the older authors concerning cancer of the thymus,

of which Astley Cooper had one case, Friedleben treats with unmistakable contempt, although to-day an experienced pathologist could hardly be in doubt that these tumors, observed in people perhaps 19 years old, which are situated in the anterior mediastinum which lie over the pericardium, which take possession of the site of the thymus, and in some measure look similar to it in structure, belong to the class of Virchow's lympho-sarcoma thymicum. The reproach that the opinions of the older authors were somewhat lacking in exactness, can surely be acknowledged, but Friedleben's interpretations of these are all the more incorrect; because, although to-day those tumors are no longer called carcinomata, yet the occurrence of malignant lympho-sarcoma is one of the best known facts that we know about the pathology of the thymus, and a denial of malignant tumors of the thymus must put in question the infallibility of Friedleben's criticism.

My second point is an observation which I find in the second volume of Virchow's "Tumors," 1866. In the chapter on hyperplasia of the lymph glands, Virchow speaks as follows, concerning *asthma thymicum*:

"This asthma has lately been much doubted, and it has been struck out from the class of disease. With Hasse⁴ I consider it possible, yet it is difficult to decide the question surely, since generally other symptoms of disease are present at the same time, which sufficiently declare the danger of the disease, viz.: spasmodic catarrh. Nevertheless, a considerable hyperplasia has its influence on the respiration and circulation; but there have been only a few cases in which I have really seen considerable hyperplasia. Yet I have seen them. In my collection I have one preparation where the child died of asthma and where the thymus was so markedly enlarged that I could not understand how the possibility could be denied that the dyspnoea arose from its pressure. The gland weighed 6.5 drachms. It was $3\frac{1}{2}$ inches long, $\frac{3}{8}$ inch thick, and $2\frac{1}{2}$ inches in its greatest breadth, with an average of $1\frac{1}{4}$ inch. In a recent case I notice that the thymus measured 6 cm. in its greatest breadth, 1.5 cm. in thickness and 7.5 cm. in its greatest length, with an average of 6.5 cm."

Thus it is seen that the measurements which Virchow has considered as sufficient for an explanation of death by suffocation, almost completely correspond with those of my second case; and furthermore, that these cases must be very rare when only two such preparations are found in the very abundant material in the Berlin Institute.

Just so little can I give satisfactory reasons why a condition which evidently is of long duration can

⁴ The book of K. Ew. Hasse: Spec. Pathol. Anatomie published in 1841, relies concerning the thymus on Becker, Haugstedt, Kopf and others, and in hyperplasia of the thymus considers of importance only in special cases the compression on the trachea; but rather on the vena cava and the right auricle.

produce so sudden death. I can only be guided by my experience, that very often have I found a satisfactory explanation of the cause of sudden death at the autopsy of young children, but every explanation is at fault concerning the question that the child was so very well immediately before the occurrence of death and then so unexpectedly and so suddenly died.

At any rate, the judicial physician's side of the question appears to me important enough to mention it here. It is proven that healthy nurslings can die a sudden death by suffocation without attaching blame to any one, or without thinking of suffocation by the mother or others; and perhaps this communication affords the opportunity of supplying a deficiency in pathological anatomy by further observations in judicial autopsies.

SOCIETY PROCEEDINGS.

Chicago Medico-Legal Society.

Stated Meeting, October 6, 1888.

THE PRESIDENT, E. J. DOERING, M.D., IN THE CHAIR.

DR. E. WYLLYS ANDREWS and DR. JAMES BURRY read a paper on

MEDICO-LEGAL ASPECTS OF SOME INJURIES OF THE SPINAL CORD.

(See page 841.)

DR. HENRY L. LYMAN made some remarks on the same subject. (See page 844.)

DR. EDMUND ANDREWS: I have been so much perplexed by this class of cases that I would a good deal rather ask questions than attempt to enlighten anybody. I was induced to come here to-night, partly, because I am threatened to be called as a witness in a railroad suit. I have not examined the patient, but it is said to be an injury of the spine, and it struck me that this discussion would enlighten me.

DR. L. L. McARTHUR: There are some facts that will bear reiteration and emphasis in this connection; and to begin the subject one might follow Ashurst, who says it is mortifying to confess that the physicians and surgeons of the present day know less in regard to concussions of the spine than their predecessors did. But he enlightens us a little further by stating that we know perhaps a little more what it is not. The improvements which have been made in the line of nervous diseases, and the advance in the pathology of the spinal cord, have enabled the neurologists to clear up many of the nervous diseases which were classed under the head of spinal concussion. Spinal concussion can be limited to

concussion of the brain, and yet, in concussion of the brain we always expect the symptoms to manifest themselves at or very soon after the injury. But in this class of cases which come under the head of spinal concussion—identically similar in their nature, that is, believed to be without any actual structural lesion of the spinal cord, they are claimed to occur weeks or months afterward. Hence, I feel inclined to ask the gentleman who closes the discussion if we have any symptoms which we may rely on as confirming, or being diagnostic of, spinal concussion? If they can in any way enlighten us as to our diagnosis for other troubles of the spinal cord, or if the neurologist has some means at arriving at a conclusion, some characteristic symptoms like vertigo, the peculiar gait of locomotor ataxia, where the gray matter of the cord is affected. There seems to be nothing definite conveyed by the term spinal concussion. Some other name has been suggested, rather than this term which covers up ignorance, and probably *comotio cerebri* might be applied, rather than that of concussion. We know that concussion of the spine is not shock. Moreover, as advances are made in medicine the list of functional diseases are disappearing. Formerly, it was satisfactory to make a diagnosis of a person being paralyzed, but the term paralysis is obsolete, and so the functional diseases are, as advances are made, disappearing. We cannot expect to have changes take place of a physiological or pathological nature without some textural change; I mean if these changes persist, are constantly making themselves evident; they cannot last four weeks. Temporarily, we might have a functional derangement of the cord in which some symptoms were manifested, but as for weeks, months and years, as in the case of Dr. Phillips, it is unreasonable, in the light of our pathological literature, to expect without some structural changes. A significant fact in regard to concussion of the spine is that such a large proportion of the cases are in connection with some suit for damages, especially those which are obscure.

DR. J. G. KIERNAN: I did not hear the paper, and am not therefore very well prepared to discuss it. With regard to one point raised by Dr. McArthur I shall have to take issue; first, as to the textural question. It seems to me perfectly possible that for a long time there may be very marked symptoms without textural lesions. Cases have been under observation in which no lesion was found, and yet in which the symptoms were well marked. I was much pleased to hear Dr. Lyman refer to the fact that many cases could be considered rather as cerebral than spinal cases. The fact is lost sight of, that when the patient recovers from cerebral concussion he passes out of the surgeon's hands. When I was connected with the institution on Ward's Island,

I remember distinctly, four recoveries from cerebral concussion that died in two or three years, under my charge in the insane hospital; they did not recover from cerebral concussion. I think if cerebral concussion was as frequently made a matter of litigation, and as frequently examined as spinal concussion a great many more cases might be developed. A large number of the recoveries drift into the insane and poor hospitals and die there.

In regard to the point raised by Dr. Lyman, particularly with respect to the cases classified as mental disorder: The fact that many of these make good recoveries, is signally shown in a case of Page's that I have always been suspicious of. Page relates the case of a woman which he decided, after careful examination, was one entitled to pretty heavy damage; she was incurable, and yet she recovered, married, had children, and lived a happy life thereafter. But, unfortunately, very often those cases do not have such a fortunate outcome. Dr. McIlvaine, at a meeting of railway surgeons, reported a case in which a woman rallied from the effects of an accident, and he believed her to be a malingerer; but finally the woman began to evince all the symptoms of advanced myelitis, and the doctor was persuaded that her disease had started at the accident to which she traced it.

With regard to mental disturbances always being evidence of direct cerebral trouble, the question is certainly one which is open to doubt. We all know who have had experience with locomotor ataxia, that there are very marked mental disturbances which occur in consequence of that disorder; they occur in typical cases, and if they can occur from a spinal disorder of that kind, why not from the condition known as spinal concussion. That there is a great difficulty in diagnosis is shown by the elevated railroad case in Brooklyn. It was a case in which a man pushed a woman down stairs. The question as to whether the case was one of spinal concussion or of hysteria was debated, and evidence given on both sides by very eminent neurologists; I think on the side of the concussion were Drs. Hammond and Spitzka, and that eminent railway expert, James J. Johnson, who has written more on the subject of spinal concussion than any other person. On the other side were Landon Carter Gray and Stein. In that case the hysterical symptoms were well marked, and yet there was some spinal disorder, as the woman died with decided myelitic symptoms.

DR. C. E. WEBSTER: I think the point Dr. Lyman advanced is one of a great deal of interest; that is, that in these cases of spinal concussion there may be a fundamental change in the nervous system of the individual, so that after the concussion or accident takes place the fundamental trend or principle of his organization may

be changed; he may be a different individual.

DR. CLARK GAPIN: On the very threshold of the subject we find this difficulty, that it is in a more or less chaotic state, and any discussion of it at present must be desultory, a sort of patchwork discussion. A few years ago we thought we were pretty well grounded, and those of us who read Erichsen at that time without any very critical feeling, accepted what he had to say, and passed it by as a subject which a master mind had solved apparently for all time to come; but a more critical investigation of Erichsen's work shows that it is a master of expression rather than a masterly statement of fact. I think Erichsen's work may be criticised in the very name which he gives to the injury; he calls it concussion of the spine. Now if any one were to approach Erichsen with that very array of symptoms relating to the brain, he would never think of calling it concussion of the brain. Concussion of the brain we are accustomed to associate with positive physical and mental manifestations, and symptoms developed at the time or immediately following the injury. In his concussion of the spine there are no such symptoms, the symptoms may manifest themselves weeks, months or even years afterwards, and he is willing to accept them as evidence of this concussion. I think not only do the symptoms not bear out the name which he has applied, but there is a very different anatomical condition. The brain is penned up in a bony covering that is very close to the brain tissue; whereas the spinal cord floats loosely in a bony casing surrounded by a fluid, and at all points it is considerably distant from its bony surrounding, hence, the greater difficulty of any concussion occurring there.

With regard to the cases that have been presented, I think that those cases in which there is a positive physical injury to the spinal cord are very rarely passed by; there is very rarely any difficulty that I have noticed. In my observation there is no dispute among surgeons where the spinal cord is injured; we know the symptoms of even a blood clot on the spinal cord is very pronounced, and they are unquestionable; yet we are asked to believe that a great injury has been sustained by the cord where there are none of these, even transient symptoms. Some time ago I had a case in which it became my duty to investigate Erichsen's cases closely. I took all the cases and arranged them under three heads: the objective symptoms, the subjective symptoms, and those which could be maligned. If you ever go through that experience you will find how comparatively few the cases are which Erichsen gives as proof of concussion of the spine.

I agree with Dr. Lyman's statement of his arrangement and classification of these injuries,

that where these symptoms follow a considerable time afterward, or where they are of a functional nature, that is to say, where there are symptoms that are elusive in their character, which you cannot grasp, they are mental in their quality, and in some cases they may all result from the injury.

Sometimes I think, from the tremendous shock of a railroad accident, this disarrangement may occur, and the individual be a sufferer for his whole lifetime, but such cases are extremely rare and generally marked by present symptoms. The other class of cases are those which arise afterwards, and heredity has a great deal to do with these cases; we find some of them are individuals who have inherited imperfect nervous organizations; we find others who have, by dissipation, brought themselves into that condition, and when they come to sue a railroad company, no matter what their past life has been, what the heredity has been, it is the fault of the railroad company.

DR. E. W. ANDREWS: All authorities, including Erichsen, himself, positively assures us that spinal injuries received in railroad accidents are in no essential way different from those received in any other manner. Cases have been cited running back centuries in medical history of exactly this injury which Erichsen describes as railway spine. In this paper we have not attempted to discuss the pathology; this is well mapped out by pathologists of note. While it is true, as Dr. Lyman states, that these cases sooner or later cease to be surgical, yet the pathology of injuries is not essentially different; that we know from the pathology of disease. In at least one disease, locomotor ataxia, there seems to be very positive testimony that injury may be the exciting, even the predisposing cause. Leyden has asserted this. Pitt is strongly of the opinion that locomotor ataxia may be produced directly by injury, and more especially he insists that a case of locomotor ataxia may, as a result of railway injury, be produced. Of course if this be the case, if a disease of the spinal tract may be produced by injury, it would be supposed that other diseases might be produced by traumatism, but necessarily an understanding of the minute pathology of the cord, and especially the microscopic appearance of the tract, would be indispensable to one who would give testimony in a court of justice in cases involving important injuries. Within a short time, to my knowledge, one expert has been trapped in this manner in an important case. A prominent railway surgeon, an expert, went on the witness stand and, with what seems like temerity, acknowledged, in testifying in relation to a case of so called railway spine, that he was unacquainted with the work of Page. Well-meaning surgeons who are willing at the present day to go into a court of justice and give the pathological

views of Erichsen, I think are liable to be sadly caught up.

In place of such terms as spinal concussion it is perhaps better to use definite descriptive compounds; intra-spinal hemorrhage can undoubtedly be applied to a large number of spinal symptoms; laceration of the ligaments can also be used. Around the spinal cord there are a set of veins that can scarcely be lacerated without producing rupture, and hæmorrhages may occur upon the membranes or in the substance of the cord. Traumatic myelitis is undoubtedly a condition which at certain levels of the cord, can exist. Gower speaks of cases of traumatic myelitis in which a post-mortem has revealed all the conditions produced in operation from thickening of the membrane there. Some slight injury to the bones is another condition. And so we may classify the actual state of the cord, and in a very large number of cases specify accurately the lesion. As to pure concussion, it may be defined as a stunted condition of the cord, which is inferred to have undergone some form of molecular derangement by which its function is for the time being stunted. Cases are probably on record in which post-mortems, after spinal injury, have failed to reveal any lesion whatever in the tissue. I question, however, whether such cases have been subjected to complete and minute microscopical examination such as is at present considered essential. Lidell has related a case in which a post-mortem examination was held on a patient who had died, as was supposed, from concussion of the cord. At first no sign revealed itself in the appearance of the cord, and yet a more careful subsequent examination showed in the interior of the cord itself a globular clot which had produced compression and death. The question of Dr. McArthur, "Does Concussion Exist?" it is perhaps impossible to answer. My present impression is that transiently it may.

I will close by saying that Sir Joseph Bryant, as good surgical authority as we have to-day, has recently written and published a paper in which he claims that concussion of the brain has no existence as a pathological state. Hilton many years ago denied that any case of death from concussion of the brain had been examined which failed to reveal structural changes in the gross appearance. The tendency of the present time is to more and more careful examination of these traumatic troubles of the brain and cord. Much of the symptomatology of concussion is inferential, but from the investigations that are being carried on we will undoubtedly be able to define a structural condition corresponding to every symptom which injuries produce.

Philadelphia County Medical Society.

*Stated Meeting, October 10, 1888.*THE PRESIDENT, J. SOLIS-COHEN, M.D.,
IN THE CHAIR.

DR. G. E. DESCHWEINITZ presented the following paper on

ACUTE UNILATERAL OPTIC NEURITIS, WITH THE
REPORT OF A CASE.

Cases of sudden failure of sight in one eye with little or no ophthalmoscopic changes are occasionally encountered, in which the attack is attributed to exposure to cold. Sometimes in these instances congestion of the optic disk is present, and a retro-ocular neuritis has taken place. Other cases of acute optic neuritis, sometimes monocular, sometimes double, are on record. Thus Max Haadel¹ observed nine cases, some single and some double, with and without defects in the field of vision, usually with serious disturbance of sight, mostly with pronounced inflammation of the papilla and neighboring retina, in which exposure to a draught of air was the imputed cause. Periostitis at the foramen opticum was doubtful, and the absence of syphilis, sugar and albumen, lead and other poisons was assured in every case. In M. Schlüter's² statistics, among thirty-eight cases of neuritis and neuro-retinitis, seven are classed as primary, while the remainder are arranged as follows: thirteen of central origin, six from specific causes, four followed as the result of pathological orbital processes, two from abuse of alcohol and tobacco, two from albumen, and one each in connection with the puerperal state, after injury, from acute myelitis, and from hereditary reasons. E. Schmidt,³ in an examination of the cases of optic neuritis in the clinic of Prof. Hirschmann, at Charkow, found, among 120 cases in which the etiology was recorded with some degree of exactness, two instances of papillitis or papillo-retinitis due to cold. Voissius⁴ has recorded a case of monocular optic neuritis in a man aged 61, the attack coming on as the result of catching cold during a long wet drive. Recovery, with a hemiopic defect in the field of vision, was the outcome of the disorder. Roi⁵ reports some examples of optic neuritis which he looked upon as rheumatic. They appeared monocular, were accompanied by a speedy diminution of visual acuity passing into amaurosis, but not, however, to the exclusion of a return to normal sharpness of sight. H. F. Hansell⁶ describes two instances

of acute optic neuritis of rheumatic origin, one monocular in a healthy married woman, and the other double in a man aged 31. In each there was sudden loss of vision, swollen optic disks, and under treatment a rapid return to normal visual acuity. In Dr. Hansell's paper references to analogous cases are recorded, and L. W. Fox⁷ has recorded an instance of acute monocular optic neuritis. Recently R. H. Derby⁸ has reported a case of unocular neuro-retinitis in a girl whose father had had syphilis, but who had no other manifestation of constitutional taint. There was at first a central scotoma, then optic neuritis. Light perception was lost, but under mercurial inunctions and iodide of potash the swelling of the disk, which had amounted to 7 D., subsided, and fair vision was recovered. Cases of optic neuritis without evident cause are occasionally recorded, as one by Power.⁹ The patient was an anæmic lad of 17; the neuritis was double; albumen and syphilis were absent; the lad had had two attacks of rheumatism and his father was gouty. Friedenwald¹⁰ describes an instance of right optic neuritis in an otherwise healthy girl of 14, preceded by violent headache and other symptoms indicating grave cerebral disturbance, but in which perfect recovery followed. He classed her case with these examples of optic neuritis, referred to by Juler, occasionally met with in young girls, the cause assigned being some menstrual disturbance, the presence of which, however, careful inquiry often fails to elicit. Usually the neuritis is preceded by severe headache and the prognosis is unfavorable. No further reference to the many cases of neuro-retinitis described in connection with irregularities of the menstrual functions need be made. Hirschberg¹¹ has seen several instances of primary optic neuritis, whose course is very typical. The disease is divided into three stages: the first, characterized by great visual disturbance, with slight ophthalmoscopic appearances; the second, by diminution of the visual disturbance and very marked inflammation of the disk; and the third, usually by almost complete recovery with pallor of the disk. The cases mostly occur in women, but are not connected with derangement of the sexual functions. Partaking somewhat of the nature of such cases, but not without a history of exposure as the exciting cause, is the subject of this communication.

Mrs. W., æt. 40, consulted me on July 11, 1888, because for a week past she had suffered from neuralgic pains in and above the eyes, most marked upon the right side. Bright light was distressing, and pain followed when the eyes were rolled upward; slight tenderness was ap-

parent when pressure was made upon the right globe. The amplitude of accommodation was 3.5 D., and there was high insufficiency of the internal recti, so that a divergent squint was evident when the eyes attempted to fix a point 15 cm. distant. The fundus of each revealed no gross lesions, save a slight retinal haze around the upper and lower edges of the right disk, the deeper layers of which were gray. The maculas were normal, and the refraction appeared to be a simple hypermetropia of 1.5 D. In the absence of any general derangement the peri-orbital pain was attributed to eye-strain, and atropia drops were ordered for the purpose of measuring the refraction error. The correcting glass proved to be + 1.5 s. and with it normal vision was acquired. During the application of the atropia the neuralgia disappeared. The drops were discontinued and the patient directed to return in two weeks. During the measurement of the refractive error, the patient, on several occasions stated that although she saw the same number of letters with the right eye that she did with the left, she failed to see them with the same distinctness; but no changes at this time were present in the fundus. This indistinctness gradually assumed the appearance of a definite, dark area in the field of vision, the peri-orbital pain returned, and five days after the last ophthalmoscopic examination had failed to discover any changes in the disk or retina, she returned with the vision sunken to ability to count fingers and well-marked right-sided optic neuritis. All edges of the disk were woolly and its upper margins entirely hidden, while a flame-shaped hæmorrhage was situated above and to the inner side. The apex of the swelling was + 3. D., the vessels were about normal in size, and the macula free from disease. The pupil was of medium size and acted sluggishly to light and shade. A few days before this time she had gone on an excursion with her children, became much overheated, and had afterward waded about in a neighboring brook. It was in the evening of this day that the neuralgia returned, the definite dark area appeared in the field of vision, and shooting pains attacked the deep muscles of the thighs. Further examination proved an entire absence of any symptoms pointing to brain disorder; the heart and lungs were normal, and the patient was not anæmic, there had been no suppression of the menstrual flow and this function was natural, no active uterine disease existed, except a slight prolapsus which was not then under treatment. The urine was free from albumen, sugar, and tube casts, and the last recent illness, several years before, had been an attack of peritonitis from which a good recovery had resulted.

Dr. James Tyson, who saw the case in consultation, confirmed the accuracy of these examinations. Syphilitic infection and the action of lead

or other poisons were carefully excluded. The vision continued to sink, and on the following day was reduced to faint quantitative light-perception and the disk, if anything, was slightly more swollen. The temple was freely leeches and the patient directed to take fifteen grains salicylate of sodium before each meal, and seven and a-half grains of iodide of potash, with one-twenty-fourth of a grain of bichloride of mercury after each meal. Three days later, or on July 30th, the vision was slightly improved to the ability to see the hand move and the pain was distinctly better. The medicine was continued and small fly blisters ordered placed upon the temple. August 1st, the salicylate of sodium was discontinued, but the other medications continued, vision improved and large letters (Sn CC) were faintly recognized.

August 6th, marked improvement, $V. = \frac{5}{xxxxv}$; edges of the disk visible all around and only a faint remnant of the hæmorrhage. August 20th, neuritis had practically subsided; $V. = \frac{5}{x}$, form and color fields normal in extent; no scotomata; ordered one-twenty-fourth of bichloride of mercury after each meal. September 9th, disk pallid, and all traces of the neuritis had disappeared.

In the absence of any symptoms pointing to cerebral disturbance, with no uterine disease save a slight prolapsus and the history of a leucorrhœa no longer active; with the menstrual functions normal; with a healthy circulatory apparatus and the urine free from albumen, sugar, and tube casts, and with the direct account of overheating and exposure, we may fairly conclude that this was an instance of genuine, acute optic neuritis. The history shows that before any ophthalmoscopic changes were evident, and before there was any positive diminution in visual acuity, the field of vision was invested with a haze which afterward assumed a definite, dark form, probably coincident with the first appearance of the inflammation around the papilla and the loss of sight. Hence it is evident that the attack was in process of formation and was precipitated by the wetting of the feet and sudden cooling after an overheating. Cases of optic neuritis apparently due to exposure, as has been pointed out by Leber and others, are mostly monocular; and rheumatism, perhaps upon insufficient evidence, has been cited as the cause. Gowers,¹² writing upon this point, says: "Neuro-retinitis has been loosely ascribed to rheumatism, but only on the ground that it has sometimes appeared to be due to cold." Rheumatic inflammation at the back of the orbit, however, according to the same author, may damage the optic nerve. Michel,¹³ commenting upon a reported case of acute, peripheral retro-bulbar neuritis, remarks that he has never observed a

¹² Medical Ophthalmoscopy, 2d ed. p. 230.

¹³ Nagel's Jahresbericht, xvii. Jahrgang, p. 381.

"rheumatic" neuritis and considers the assertion of such as a mark of ignorance of the causes especially operative in the production of inflammation of the optic nerve.

Hansell (*loc. cit.*) thinks "that a true rheumatic inflammation of the fibrous coat of the nerve between the optic foramen and the sclerotic" quite possible, but owing to the infrequent opportunity for section and examination admits that "our pathology is, at best, speculative." The central scotoma which existed in this and similar cases denotes an affection of the sheath of the nerve extending into its substance, not as Hirschberg remarks, as would have been supposed before the macular fibres were discovered, a central inflammation extending outward. The prognosis depends to a certain extent upon the site of the lesion and the termination may be favorable, as in the case reported, or a permanent atrophy of the disk may result. Hirschberg (*loc. cit.*), in his cases of primary optic neuritis, has found usually that the second eye is attacked; the interval may be days, or weeks, or months. Three of his cases illustrate this fact. A woman, aged 42, suddenly lost the sight of the right eye; in six days from the beginning of the attack this was well, but the left eye was attacked and optic neuritis developed; in three weeks recovery had taken place and the fundi were normal. In a second case a woman, aged 20, had slight temporary loss of vision in the right eye three weeks before coming under observation for loss of vision in the left, which came on eight days before. Four months later she came with the right eye similarly affected, while the left had practically recovered. A third instance was that of a peasant girl, aged 17, who had her right eye attacked in 1878, recovered, and in 1884 had her left eye attacked, which also recovered. The treatment has already been discussed. Leeching of the temple, followed by blisters, diaphoresis, together with the salicylates and iodide of potash, yield the best results. Improvement may take place before the remedies have time to take effect.

DR. RANDALL: I can add nothing to Dr. de Schweinitz's admirable presentation of the subject; but would like to reiterate the importance of early recognition and prompt treatment of such cases. I feel very sure that the issue depends very largely upon whether early alterative treatment is instituted, since upon the limitation and prompt removal of the exudation in the nerve and retina depends the possibility of a return to the normal with preservation of the sight.

DR. JAMES K. YOUNG exhibited the

MORTON OPHTHALMOSCOPE.

The Morton ophthalmoscope presents some new features which may be of interest to some of the members of this Society. It is made by Pickard & Curry, London, and as an instrument is well

balanced, fits the eye well, and as a piece of mechanism is perfection itself. It is a modification of the Gower's ophthalmoscope, as are all modern English instruments, but in the position and movement of the lenses differs from this and all others. The Rekoss disk is there replaced by an elliptical trough containing the lenses. These are simply confined in the channel, are unattached to each other, and are moved by a wheel below, and pass around a wheel above. In this respect it resembles the Couper instrument, in which the lenses are attached to one another as an endless chain, but is an improvement in the right direction. It has, in all, thirty-three lenses. In the trough are eighteen concave lenses from -0.5 to 30 D. Eleven convex lenses from $+0.5$ to 12 D., and on the disk has four additional lenses, a -10 D. and -50 D., and a $+0.5$ and $+20$ D. These admit of as many combinations as any instrument I am familiar with. It has three mirrors, a small concave mirror of about 6 cm. focal length, fastened to a collar, a large concave mirror of about 29 cm. focal length, and a plane one. These are all attached, and the apertures come readily over the sight hole. It has below the index dial a pupillometer, which adds to the usefulness of the instrument. It fits accurately into a rosewood case, and has a convex lens for indirect method.

DR. RANDALL: I feel that a discussion of minutiae as to the ophthalmoscope is hardly in place; but as to the point emphasized, that the instrument contains a concave lens of fifty dioptries, I must confess my scepticism as to its value. Cooper put a concave 72 D. in his instrument and told me that he was self-condemned as an ophthalmoscopist in having nothing stronger than 24 D.; yet when asked if he ever had use for the strong lens, admitted that a case calling for it was seen but once or twice a year. Even should one of the very rare cases of high myopia be met, the eye-ground would be better seen (if at all visible in the upright image) by placing a strong concave lens close in front of the examined eye.

DOMESTIC CORRESPONDENCE.

The Medical College of Virginia.

Dear Sir:—There has appeared in THE JOURNAL several articles reflecting upon the Medical College of Virginia, which are so flagrantly at variance with the truth, that the Faculty feel called upon to make the following statement of the facts, which the writer in THE JOURNAL has distorted in many ways. It is only in deference to the official position of THE JOURNAL as the accredited organ of the Medical Association that it is deemed necessary to notice these attacks, for the individual opinions of the author are simply a matter of indifference to the Faculty, being palpa-

bly the reflex of an inimical partizanship in this city.

Briefly put, the Medical College of Virginia is charged by its enemies:

1. With being hostile to the principles of the higher standard of medical education than at present obtained in the examinations of the colleges.

2. With being opposed to the establishment of a State Medical Board in pursuance of that object.

3. That it attempted, through its students, at the last session of the Legislature to amend the law, so far as to substitute for it the proposition to exempt Virginia students from its operations.

In denial of these assertions it is well known that the Medical College was one of the prime movers in getting the law passed by the Legislature, and, but for the zealous personal exertions of the members of the Faculty, that it would have failed to be enacted. After an experience of two years, it was found to be so very imperfect in many of its features that the Medical Society of Virginia and the Examining Board came before the Legislature asking that it be amended; the Board wishing to have the feature permitting an applicant to appear before any three members individually, instead of the entire Board, abolished; and the Society asking that the number of members of the Board be reduced from thirty to twelve, and that a diploma should be a preliminary qualification.

The students at the time the amendments were before the Legislature were incensed at the action of the Board at its last session when applicants from this College were rejected on account of what they believed was personal hostility of three of the members to the Faculty, and fearing that in future examinations the students of this College would be vicarious sufferers for such animosity, petitioned the Legislature to exempt the graduates of the two State institutions from the operation of the law.

A committee of the students waited upon the Dean and requested the co-operation of the Faculty in their movement, but were plainly and positively told that the College was committed to, and believed in the principles of the law, and therefore could not aid them in their attempt to abolish it or to get its students exempted from its operations. The Faculty, however, at the same time, claimed the same liberty of opinion in discussing the proposed amendments that were being offered, as other members of the profession, and did not concede that an objection to two or three members of the Board implied any hostility to the wish "to elevate the standard of medical education." To emphasize this fact, the Dean was instructed to appear before the Legislature and re-affirm the wish of the Faculty that the law, imperfect and unsatisfactory as it was, should remain in its original form rather than encounter

the risk of defeat in contentions over the amendments. Had it been the wish of the Faculty to oppose the passage of the bill, it will not be denied that there would have been any difficulty in defeating it, as a large number of legislators deferred to its wishes in the matter.

The writer in THE JOURNAL persists in placing the Medical College of Virginia in a false attitude in stating that the percentage of its graduates before the Examining Board was so small as to establish its meagre teaching qualifications in comparison with other institutions in the country, whilst the facts are, as the following report of the Examining Board will show, that it had the smallest number of graduates rejected of any other college whose number of applicants were equal to it.

Number of Applicants examined by Board in Session. 123

N. B.—The first and second columns add up 243 and 184 respectively; but three of the applicants each gave two Colleges of graduation.

It will be seen from the above table that 57 students of this College were examined by the Board, and about 7 per cent. were rejected, but that of the rejected three were re-examined five months after-

wards and were given their licenses. The statistics regarding the students from Baltimore, Philadelphia and New York show a rejection of 25 to 30 per cent.

At the examinations in April last the State Medical Examining Board gave certificates to practice medicine to three of the students of this College whom the Faculty the week previous had rejected for not reaching the standard required by it.

We shall pass by in silence the prophecies of the writer in *THE JOURNAL*, that the Faculty of the College intended going to Norfolk for the purpose of attacking the Medical Board and preventing its renomination, considering it necessary only to refer its readers to an accurate report of the meeting, where Dr. Cullen, the Dean of the Faculty, seconded the resolution of Dr. Chancellor for the reappointment of the entire Board, and embraced that opportunity of refuting the misrepresentations in regard to the action of the College, which was received by the Society with great gratification and satisfaction. Dr. Cullen, in substance, stated to the Society what is written here, and added that not only was the Medical College of Virginia in accord with the examining law of the State, but that it would go further than it does and join the Medical Society of Virginia in petitioning the Legislature to compel the two State institutions to have preliminary examinations and a three years' graded course. I am very respectfully yours,

J. S. DORSEY CULLEN,

Dean of the Faculty, Medical College of Virginia.

MISCELLANEOUS.

TYPHOID FEVER seems to have taken possession of Providence, R. I. From September 1 to December 5 more cases were reported than since the epidemic of 1882, which followed a very heavy rainfall, but the rainfall for the past three months breaks the weather record, and in this connection it is significant that typhoid is increasing very rapidly. From December 1 to December 5, 37 new cases were reported. It seems that the warning of Health Officer Chapin has not been heeded. In his last report he says: "The Board of Public Works reports that they have during the year succeeded in removing all the privies from the banks of the Pawtuxet River. There are, however, certain places where drainage may at times get into the river, or where it may be washed in during freshets. The bleacheries, dye works and wool scouring works still discharge their effluent into the river. It also happens that occasionally dead animals, slops, night-soil and other offensive matters are thrown in. Much of this pollution can be prevented by a continued inspection of the banks of the stream, and I am glad to be able to report that the Board of Public Works have detailed a man for this purpose. Still, it cannot be hoped that every source of pollution can be permanently removed from a river flowing in such a thickly settled region, and through so many manufacturing villages as does the Pawtuxet. The danger of pollution, either accidental or intentional, will always be considerable, and we must remember that in epidemics of typhoid fever in other cities and towns, a single case of the disease, on the banks of the stream

which serves as the water supply, and that, too, far above the intake, has been clearly proved to be the cause of the outbreak. Such being the case, we cannot afford to run any risks, and if the improved methods of precipitation and filtration which have been recently brought into use are what is claimed for them, it would be highly advantageous if they could be adopted here. As in addition to removing disease germs, such methods render the water clear and free from sediment, their adoption would be most acceptable to our people. The subject is one that should receive careful and immediate investigation. While it may be possible to filter the water on a large scale before it enters the mains, the use of domestic filters on the house taps is not only useless, but dangerous, and has been discouraged by this Department on all occasions." Dr. Chapin said that the importance of thoroughly boiling Pawtuxet water before taking it into the system could not be too strongly emphasized. While boiling may not improve the taste of the water, it will generally kill the germs of disease it contains.

EXPOSURE OF A QUACK.—Aaron Geismar, alias Dr. Geismardo, alias Professor Albert Le Grand, alias Professor Ernest De Blanc, who is known in Chicago, has come to grief in New York at the hands of Miss Nellie Bly, a newspaper writer. He had announced in a flaming advertisement as follows:

PROF. ERNEST DE BLANC,
the Famous Chevalier Electrician of Paris,
will exhibit HIS SKILL AND TREAT THE AFFLICTED FREE on the stage
IN VIEW OF THE AUDIENCE.

Nellie Bly visited his house and discovered that his electric apparatus consisted of a battery in a back hall of his house, and a nickel-plated spring at the door by which he turned the electricity off and on. By means of wires (concealed by a rug) in the floor, he would apparently act as a living battery upon his patients. This discovery led to the disclosure of his life of fraud. He started out in Portland, Ore., several years ago, as Dr. Geismardo. While there he assaulted one of his women patients and was imprisoned. Next he appeared in San Jose, Cal., where he made a sudden departure with money advanced for treatments which he never gave. He turned up at Toledo soon after and announced his lectures and treatment, but did not put in an appearance at the hall. In July last he was billed in Buffalo as Professor Albert Le Grand. On that occasion the Chicago *Herald's* Buffalo correspondent telegraphed the following:

Dr. Edward Storek, chairman of the Erie County Medical Censors, to-day gave "Professor" Albert Le Grand notice to leave town or be arrested for practicing without a diploma. Le Grand gave free lectures in Music Hall, and claimed to cure the lame, halt and blind in Biblical fashion. Dr. Storek said: "Professor Le Grand has decided to leave the city within twenty-four hours. He admitted to me that he had no diploma, and that he was no physician, but a healer. When I asked him if he did not take fees he said that he did. Then, after a good deal of bluster, he gave in. I have learned some of his history. He was a Dr. Geismardo in Portland, Ore., and claimed to be a member of the Society of Sciences of Paris. He also exhibited a decoration, which he claimed to be a cross of the Legion of Honor. He left that city under a cloud. He then turned up in Denver, St. Louis, Kansas City, Baltimore and Boston. He was also arrested in Milwaukee. The society could prosecute him here if it wished to, but if he leaves the city that will be enough. Le Grand speaks French fluently, and owned up to me that his magnetic touch was caused by an electric belt concealed in the palm of his hand. He had three or four dummies traveling with him who came upon the platform and were cured by him.

In July the "doctor" made his appearance in New Orleans. He spent considerable money in advertising, hotel expenses, and theatre rent, but had to leave the city

before getting any returns on account of previous swindlings in that city. Finally he went to New York, and there his whole record has been made public.

HEALTH IN MICHIGAN.—For the month of November, 1888, compared with the preceding month, the reports indicate that tonsillitis increased, and that typho-malarial fever, diarrhoea, dysentery, cholera morbus, and cholera infantum decreased in prevalence.

Compared with the preceding month the temperature for the month of November, 1888, was lower, the relative humidity was more, the absolute humidity and the day and night ozone were less.

Compared with the average of the month of November, in the nine years, 1879-87, diphtheria, intermittent fever, consumption of the lungs, typhoid fever, pneumonia typho-malarial fever, whooping-cough, and remittent fever were less prevalent in November, 1888.

For the month of November, 1888, compared with the average for corresponding months in the nine years, 1879-1887, the temperature was slightly higher, the absolute humidity was slightly more, the relative humidity about the same, and the day and the night ozone were much less.

Including reports by regular observers and others, diphtheria was reported present in Michigan in the month of November, 1888, at twenty-six places, scarlet fever at forty-one places, typhoid fever at twenty-three places, measles at six places and small-pox at seven places.

Reports from all sources show diphtheria at ten places less, scarlet fever at nine places more, typhoid fever at twenty places less, measles at one place less, and small-pox in seven places more in the month of November, 1888, than in the preceding month.

YELLOW FEVER IN CUBA.—A Washington physician who is well informed upon West Indian affairs, says an Eastern paper, makes the surprising statement that the native Cubans do not desire to stamp out yellow fever. They suffer but little from it themselves, and are glad to have it kill about 1,000 Spanish soldiers every year. If this is true it is a shocking example of the possible results of race and national prejudice. Cuba is the fever's winter home, and from there every summer it begins a raid upon our Southern cities. It may yet become necessary to annex the island to the United States in order to have it put under proper sanitary condition. As this does not appear to be practicable at present, the best course now open is to take precautions for keeping the infection out of our country next year. Early in the season a rigid quarantine should be established, and the authorities of all Southern cities liable to visitation should see to it that all filth is removed from the streets before it can harbor and propagate the dreaded disease.

THE PENNSYLVANIA STATE INSANE HOSPITAL.—The Trustees of the State Hospital for the Insane at Norristown held their regular monthly meeting on Dec. 8. Dr. Chase reported 848 patients in the male department at the end of November, and Dr. Alice Bennett reported 827 patients in the female department. The physicians report the general health of the patients exceptionally good. Dr. Chase recommended that photographs be taken of the patients in order to keep the likenesses with the record in order to distinguish those of the same name, and to be used in case a patient escapes, and the recommendation was voted down. Trustee Stinson remarked, "we want no rogues' gallery here." The report of the Trustees concludes as follows: The Hospital has now a population of 1660 patients and if the natural increase of the insane population of the district is to be provided for it will be necessary to put up an additional ward and supply buildings. The Trustees believe that they can put up these buildings to accommodate 660 patients, 330 of each sex, for about \$400 per bed. They therefore recommend to the Legislature to appropriate \$250,000 for that purpose.

DR. A. F. RITCHIE has resigned the Chair of Anatomy in the Medical Department of the University of Minnesota.

INFLUENZA is reported to be epidemic at Fort Dodge, Iowa, and in its vicinity.

HEAD-CHEESE POISONING is reported at Brush Creek, Iowa, there being about 30 cases, none serious.

A **CODE OF VACCINATION RULES** has been adopted by the Board of Health of Columbus, Ohio, in regard to the pupils and teachers in public schools. A system of house inspection has been adopted, and is being carried into effect.

DR. R. S. SABIN, aged 56, of West Troy, a graduate of the Albany Medical College, died on Dec. 4.

A **NEW HOSPITAL** has been erected at South Bay City, Michigan.

Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department U. S. Army, from November 30, 1888, to December 7, 1888.

Major John W. Williams, Surgeon U. S. Army, is hereby relieved from further duty with the battalion of the Second Artillery at Ft. Wadsworth, New York Harbor, and will proceed to join his permanent station, Jackson Bks., La. Par. 3, S. O. 256, Hdqrs. Div. of the Atlantic, Governor's Island, New York City, December 5, 1888.

First Lieut. Robert R. Ball, Asst. Surgeon, leave of absence granted in S. O. 129, Dept. of the Missouri, October 18, 1888, is extended one month. Par. 11, S. O. 279, A. G. O., Washington, November 30, 1888.

Official List of Changes in the Medical Corps of the U. S. Navy for the Week Ending December 8, 1888.

Surgeon J. F. Bransford, detached from Smithsonian Institution and granted six months' leave, with permission to go abroad.

Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine Hospital Service; for the Two Weeks Ending December 8, 1888.

Surgeon G. W. Stoner, when relieved, to proceed to Detroit, Mich., and assume charge of the Service. November 26, 1888. Granted leave of absence for thirty days. November 28, 1888.

P. A. Surgeon D. A. Carmichael, granted leave of absence for thirty days. November 27, 1888. Relieved from duty at Washington, D. C.; ordered to Marine Hospital, Wilmington, N. C. December 3, 1888.

P. A. Surgeon S. C. Devan, detailed as attending Surgeon and acting Chief Clerk Marine Hospital Bureau. December 3, 1888. Granted leave of absence for eight days. December 8, 1888.

P. A. Surgeon F. M. Urquhart, to proceed to Evansville, Ind., for temporary duty. November 30, 1888.

P. A. Surgeon S. D. Brooks, granted leave of absence for thirty days. December 8, 1888.

Asst. Surgeon Seaton Norman, ordered to examination for promotion. November 27, 1888. Granted leave of absence for twenty-five days. December 8, 1888.

Asst. Surgeon J. B. Fattie, ordered to examination for promotion. December 7, 1888.

Asst. Surgeon G. M. Magruder, relieved from special duty at Way Cross, Ga. December 8, 1888.

Asst. Surgeon J. J. Kinyoun, granted leave of absence for ten days. December 8, 1888.

Asst. Surgeon G. T. Vaughan, granted leave of absence for twenty-three days. December 8, 1888.

Asst. Surgeon G. M. Guitéras, to proceed to Savannah, Ga., for temporary duty. December 3, 1888.

ADDRESS IN SYPHILOGRAPHY.

SYPHILIS AS A NON-VENEREAL DISEASE.

Address of the Chairman at the first session of the Section on Dermatology and Syphilography, at the Thirty-ninth Annual Meeting of the American Medical Association, Cincinnati, May 8, 1888.

BY L. DUNCAN BULKLEY, A.M., M.D.,
OF NEW YORK.

Gentlemen :—It gives me special pleasure to address you on this occasion, marking as it does an epoch in the history of the American Medical Association, which consequently should be regarded as an event of importance in American Medicine. We gather here to-day at the first meeting of the Section on Dermatology and Syphilography, of the American Medical Association, and in a measure to celebrate the recognition of this branch of medicine as a special department by the great representative medical organization of America. It is, therefore, an occasion in which those interested in this department of study and practice should feel a peculiar interest, and should particularly rejoice, for it certainly indicates an advance in medical thought and liberality, a broadening of the field of work of our Association, and, it is to be hoped, a benefit to the profession and community.

I will not occupy your time by tracing the rise of American dermatology, or detailing the elements which have contributed to bring it to its present position, as these topics have been freely handled by abler pens than mine in the Addresses of the Presidents of the American Dermatological Association, nor shall I attempt to present a sketch of the recent progress in this department, as is frequently done in such addresses, for the present current literature and the rapid multiplication of text-books renders these *résumés* less necessary and of less practical value. But I shall shortly direct your attention to a subject which I trust will prove as interesting to you as it has been to me, and which, I hope, may be the means of ultimately effecting some good. The present Section is organized for work, for the practical consideration of topics related to diseases of the skin, and it is hoped that it will contribute greatly to making dermatology a more interesting and

successful field of labor, not only to those particularly engaged in this line of practice, but also to the general practitioner, to whom this branch often presents unusual difficulties.

The title which has been given to this Section is that of Dermatology and Syphilography, in order, no doubt, to directly interest the largest number of persons possible, who might not otherwise consider that syphilis belonged properly to this Section. While there is no practical objection to the name as it now stands, it is in a measure tautological, for syphilis should in reality be no more specially mentioned than any other one of the great diseases which affect the skin, although it is undoubtedly the most important of all, and ranks hardly second to any other disease affecting the human race, both in its clinical and pathological importance. But syphilis belongs naturally to this group of diseases for reasons which are easily seen. Thus :

1. In a very large share of instances the disease gains admission through the skin, or contiguous mucous membrane, and the primary lesion then resulting becomes a sore or ulcer which is diagnosed from other cutaneous ulcerations which may resemble it.

2. Syphilis almost invariably exhibits an eruption on the skin at some period during its existence, and the manifestations of syphilis on the skin are among its most constant symptoms, far more certainly than can be asserted of any other organ or tissue of the body.

3. Syphilis is almost always diagnosticated by means of its cutaneous lesions, indeed it is generally questioned very seriously if the patient has had syphilis if there are no lesions of the skin, past or present, from which to form a diagnosis.

Syphilis has heretofore been regarded principally as a venereal disease, and is found treated of specially in works relating to this subject. But in the light of our present knowledge of the disease and the frequency with which it is communicated innocently, both by contagion and inheritance, we are no longer justified in regarding it solely as an accompaniment of vice, or the scourge of those who have committed sexual errors. In the further development of the subject I will briefly present some of the recorded facts in regard to

SYPHILIS AS A NON-VENEREAL DISEASE.¹

In using the expression "non-venereal disease" in this connection I refer, as may be imagined, to the communication of syphilis by other means than illicit sexual intercourse, for marital syphilis, as will be seen, furnishes annually a very considerable number of cases of syphilis innocently acquired.

The subject of hereditary syphilis, or the transmission of the disease to the offspring by either or both parents is a very large field of study and need not be entered upon here, as the non-venereal origin of syphilis in the vast army of these innocent victims in years past cannot be called into question; as a single instance may be mentioned, the records of the Moscow Hospital, where in eleven years there were 2,002 children born with syphilis, of whom 1,425, or 70 per cent., died.²

Fournier³ has recently furnished some interesting data in regard to the proportion of cases of innocent syphilis occurring among women, which may be briefly alluded to. The statistics were taken from 887 cases of syphilis in females in his private practice, where notes of the cases were kept; among these it was found that the disease was communicated in a non-sexual manner in 45 cases, or 5.07 of the entire number, as follows:

In domestic contagion from nurslings, children, wet nurses or nursery maids with syphilis (all the cases occurring in married women or young children)	12
Syphilis transmitted to nurses by children hereditarily syphilitic	8
Cases of hereditary syphilis	7
Cases of midwives infected on the finger in the exercise of their profession	5
Cases of syphilis acquired accidentally in infancy	4
Syphilis communicated by vaccination	2
Cases of syphilis communicated by Eustachian catheterization	2
Case of syphilis communicated by rape	1
Unknown, but non-venereal origin	4

Total cases of non-sexual syphilis, 45

Among the remaining 842 cases there were 220 women known to be married, from whose histories conclusions were drawn, doubtful cases being excluded. Of these 220, 56 were further excluded, as having either contracted syphilis from a lover, or for other reasons, leaving 164, or 20 per cent. of all the women who were infected honestly and innocently in their marriage relations through no fault of their own. Adding this to the 5 per cent. already considered, Fournier concludes that in about 25 per cent. of all cases in females, syphilis is acquired innocently and undeservedly.

The proportion of cases of syphilis in males where the disease is thus acquired is undoubtedly smaller than in females, but it is probably much

greater than one would imagine who had not considered the subject. Several years ago I presented data in regard to the cases of extra-genital chancres which had passed under my observation, before the New York State Medical Society, and the number of cases then reported, namely, 27, has since been swelled to 58. Now, of these 58 cases, no less than 30 were in males, to 28 in females. If the records of extra genital chancres in males occurring in literature are carefully studied it will be found that the number is really very large where the disease has been acquired in a perfectly innocent manner. As a single illustration of the infection of males in this manner, it may be mentioned that in several of the epidemics of syphilis from vaccination, lactation, breast drawing, and the like, it has been repeatedly recorded that several of the women who became infected communicated the disease innocently to their husbands, by means of a chancre of the penis.

The modes and methods by means of which syphilis has been communicated innocently are almost beyond the comprehension of one who has not given thought or research to the subject, and the instances are multiplying in recent literature in a most remarkable manner; showing that, so far from there being less danger than in more ignorant times, the actual instances are increasing as the advance of civilization furnishes new opportunities of immediate or mediate contact and inoculation.

Time will not suffice to enter at all fully into the subject before us, much less to give details of many illustrative cases, but I will endeavor to indicate the lines or directions in which, from past experience, infection may be most commonly expected. Three main groups or varieties of cases of non-venereal infection of syphilis may very readily be made out, according as the inoculation takes place:

1. Among those having common relations, and through the bonds of common interest in domestic and industrial life; to this class the term *syphilis economica* has been given.

2. Among infants and those having to do with their care and nourishment, or *syphilis brephotropica*, and;

3. In connection with the various forms of body-service, medical, and surgical, or of like nature—*syphilis technica*. In each of these groups we will find a large number of subdivisions, amounting to over one hundred, representing different modes of communicating the disease which have thus far been found recorded in literature. These divisions may now be considered a little more in detail.

1. *Syphilis Economica*.—Here we have the instances of the spread of syphilis in the family by the common and necessary relations of life, and in the extension of the family relation to the various groups of industrial pursuits; and further,

¹ The limits of this Address permit of but a short synopsis of the matter which has been prepared on this subject, and only the briefest outline of the data can be given.

² Quoted by Sturgis. Appendix to Diday on Infantile Syphilis, New York, 1883, p. 265.

³ Fournier. Annales de Dermat. et de Syph. Tome viii, No. 12, 1878. New series, p. 757.

the communication of syphilis from one individual to another in the different conditions of individual life. Time forbids more than a mention of the ultimate data belonging to these main groups, most of which have been corroborated by a number of instances reported by different observers. Under implements and vessels we find spoons, knives, forks, cups, glasses and jugs. Tobacco pipes have been the very frequent means of transmitting the disease, and it has also been conveyed by means of cigars, both when passed from one smoker to another, and also when fresh from the manufacturer. Torches passed from mouth to mouth have also been the means of conveying syphilis. Wearing apparel, such as shirts, drawers, pantaloons, bathing-suits, also handkerchiefs, gloves and masks, have all served to convey syphilis; as also lint, plaster; likewise bedding and toilet articles, such as sheets, pillows, towels and sponges, together with combs, syringes and tooth-brushes. It is a little remarkable that privy seats and public urinals, which are popularly supposed to be a fruitful source of infection, are found very rarely referred to in a serious manner, and really not a single well authenticated case has been met with recorded in literature, even after a most diligent search during the past three years; a rather striking illustration of the fallacy of popular impressions or beliefs. As more curious methods of conveying the syphilitic poison may be mentioned an opera glass, and a cane.

The next group, relating to industrial transmission of syphilis, includes some most interesting data. Here we find quite a large class of cases, made up of a number of trades or occupations, where the poison is conveyed through the mouth, by the use of necessary implements of the calling. Thus, the well known glass-blowers' syphilis has in times past been conveyed to a very considerable number of persons through the common use of the pipe employed; a total number of at least 162 cases have been found reported, there being repeatedly small epidemics of syphilis from this cause. At one time, when from twelve to fifteen men were thus infected in one factory, there were also five or six of their wives who received the disease again innocently from them, besides many children. Cases are reported where assayers and goldsmiths have been infected from blowpipes used in common, also an instance where the whole family of a weaver received syphilis from a pipe used to sprinkle the cloth, it being passed from mouth to mouth. Musicians have acquired the disease through the mouth-piece of their instruments, and a car-conductor by means of a whistle borrowed from a syphilitic friend. A curious method of the transmission of syphilis is found in an instance where three furriers acquired chancre in the lip by means of the thread which was drawn through the lips and bitten off; the thread abraded the lips and at the same time conveyed

the poison. A case is reported where a maker of artificial flowers was infected through her handiwork, and an instance where tack-nails passed from the mouth of one upholsterer with mucous patches to another conveyed the poison to abrasions caused by the nails.

A number of cases are on record where pens, pencils and paper-cutters put in the mouth have carried the poison of syphilis, and one where a piece of lip-glue used after a syphilitic was the means of transferring the poison. A single case, not over-carefully recorded, has been found where syphilitic inoculation was chargeable to a coin put in the mouth, but no instances have been discovered where paper-money conveyed the poison; this is not a little remarkable in view of the frequent habit of wetting the fingers on the lips in handling paper-money.

Laundresses have been reported as acquiring syphilis through their occupation, but the instances are very rare and sometimes dubious. Bundles of cast-off clothing and rags have also been infected thereby, and in one instance it is alleged that the *acarus scabiei* conveyed the poison. This latter, however, seems extremely improbable, as it is far more likely that the virus was transferred by scratching to the interdigital space where the chancre appeared.

We come next to the group of cases pertaining to individuals in various conditions in life, which relates to the personal transference of the poison by kissing, biting, scratching, pinching, and contact of parts. Kissing affords a most prolific source for the propagation of syphilis, and probably comes next to the venereal act in point of frequency of cases thus acquired. The number of instances of this on record is very large. Biting has also furnished a large number of cases, and a case is on record where the disease was communicated intentionally by a bite, the giver being actuated by personal spite and hatred. Scratching and pinching, and also individual contact in carrying one person by another, have all furnished cases of non-venereal syphilis.

2. *Syphilis Bephotrophica*.—The nutrition of and attendance upon infants has always been a very fruitful source of the non-venereal transmission of syphilis, and literature is full of accounts where not only single cases or groups of individuals have been thus infected, but even where syphilis has by this means become almost epidemic, many being attacked before the real nature of the disease was recognized and its progress arrested. Wet-nurses acquire the disease from infants, who may either be hereditarily syphilitic or who have acquired the disease in some of the many manners to be mentioned later. Infants receive syphilis from wet nurses, generally through chancres or mucous patches on the breasts, the nurse having acquired the disease either in married life, or from a syphilitic child, or in other manner.

A number of epidemics are on record where from sixteen to twenty-three persons have thus acquired the disease, started by a single syphilitic child, and in the celebrated "Pian de Nerac," occurring in a town in the southeast of France, more than forty women and children were infected, besides a number of husbands and others who concealed their disease.

Hand feeding has frequently been the means of communicating syphilis through the agency of feeding bottles, sugar-teats, cups, spoons, etc., of which many reports are found in literature which need not be here detailed. A single illustration may be given of a case observed by Hutchinson: A woman bore a number of syphilitic children as a result of the disease occurring before marriage. Her husband escaped infection until he acquired a chancre of the tonsil from his habit of starting the feeding-bottle with his mouth, in the night, for his fourth child, who was at that time suffering from a syphilitic mouth. Multitudes of instances are on record where the child has acquired syphilis through feeding implements.

The various offices and relations connected with attendance upon children are also often the means of propagating the disease between them and attendants. Cases are on record where wash water, sponges, syringes, combs, napkins, clothing and other articles have served as the means of conveying the contagion in one or the other direction. The various modes of contact between infants and adults in caring for them have also afforded opportunities for the transmission of syphilis. Thus a case is reported by Waller, where an old woman aged 70 years contracted a chancre on the left cheek and one on the left neck, at points where she was accustomed to hold a syphilitic infant in quieting it to sleep, and a number of instances are on record where a chancre has occurred on the forearm from contact with a diseased infant in carrying. Scratches and tooth wounds inflicted by syphilitic infants have repeatedly given rise to chancres, while a large number of cases are to be found where infants have received an extra genital chancre from the kissing and fondling of syphilitic adults.

3. *Syphilis Technica*.—The third main class of cases of the non-venercal transmission of syphilis relates to the acquiring the disease in connection with the various forms of body service, medical and surgical, or in others of like nature, as by nurses and attendants. Here we find three very clearly distinguishable groups of instances: 1. Where the operator is the victim; 2, where the operator is the syphilifee; and 3, where the operator is the medium.

Syphilis has been acquired by physicians and others in the pursuit of their profession in almost numberless instances, and often in a most unexpected manner. Surgeons have received the poison through wounds during operations, and an-

atomists during dissections. It is also sometimes acquired in manipulative procedures in spite of the utmost precaution. Jullien⁴ relates a case where an eminent specialist had a slight bleeding lesion on the finger and was called upon to examine a chancre upon the upper surface of the glans penis. He held the wounded finger carefully aloof from the sore, but during the examination he found that there was a second chancre of the scrotum which had just come in contact with the abrasion which he had striven to protect. Recognizing the danger, he at once washed carefully and cleansed the part thoroughly, but all in vain, as a chancre formed on the wounded part and the syphilis ran its course.

Accoucheurs and midwives furnish by far the largest number of cases of infection of this class, and literature is full of accounts of the same; personally I have seen five or six cases of digital chancre in physicians which had this origin, one of whom infected his wife. Dentists also occasionally acquire chancre of the finger from infection from mucous patches in the mouths of those on whom they are operating.

Chancres have also been produced upon the eyelids, nostrils, and lips of physicians and attendants by conveying the virus on the fingers to the parts infected, and instances are on record where the patient, while coughing, has projected the poison in the physician's face and a chancre of the eyelid or elsewhere has resulted. On one occasion a physician acquired a chancre of the tonsil from practicing artificial respiration with the mouth on a syphilitic child. Many instances may be found where individuals have become infected in the practice of breast drawing with the mouth, and also by sucking recent wounds.

The next class of cases in this group refers to those in which the operator serves as the syphilifer, and communicates his own disease to others; of this variety there are large numbers of instances on record. We have already noticed that accoucheurs and midwives often contract syphilis in their calling, and numerous instances are on record where they have been the means of spreading the disease to others, and even in large numbers. The celebrated epidemic at St. Euphennie, in France, was of this nature. A midwife acquired a chancre of the right index finger, followed by a full attack of constitutional syphilis. She still practiced her calling for four months, and communicated syphilis to more than fifty women, and through them at least thirty others were infected. In another epidemic in France over 100 were infected with syphilis, and very recently Klein⁵ reported an epidemic in England where thirty married women, nine husbands, and two

⁴ Jullien. *Traité pratique des Mal. Vénér.* 2d edit., Paris, 1886, p. 537.
⁵ Klein. *Brit. Med. Journal*, January 20, 1883.

infants contracted syphilis, directly or indirectly, from a diseased midwife.

Another very fruitful source for the propagation of non-venercal syphilis has been found in the operation of breast-drawing by the mouth, which has been mentioned as sometimes giving rise to syphilis in the operator. This practice is less common in this country and among the more highly civilized people than among the peasantry of European countries, where it has sometimes given rise to epidemics of syphilis of considerable size. As early as 1654 an event of this nature was recorded, where a professional breast-drawer infected many nursing women with chancre of the breast, and these in turn infected their nurslings, who communicated the disease to many others. An epidemic of this kind is reported by Leloir⁶ as occurring as late as 1880, where a woman acquired a chancre of the lip, and she infected four women, who in turn gave the disease to three nursing infants, one of whom, as also one of the women, died of the disease; one of the infants infected its father through the nursing-bottle and another infant gave the disease to its wet-nurse, who again transmitted it to her own infant. Many more most interesting illustrations could be given but for want of space.

A rather curious mode of propagating syphilis innocently is found in the practice of removing particles from the eye by means of the tip of the tongue. In two small villages in Russia, Tep-ljaschin⁷ found, among a population of 532 persons, no less than 68 individuals, 23 males and 45 females, affected with syphilis, about one-quarter of them being under 10 years of age. One-half of the entire number had been infected directly by a female quack who had followed the industry of removing foreign bodies from the eye, and treating trachoma, with her tongue. The woman became infected in her calling, and pursued it while diseased, with the results mentioned. A number of single instances of the same method of infection have been recorded, two of which occurred in this country.⁸

Wound sucking, which has been mentioned as giving syphilis to the operator, has also been the occasion of communicating the disease to the person operated upon.

Tattooing has been reported as the means of conveying syphilis by a number of observers, and a total of no less than 67 recorded cases has been found; as is well known, the poison is conveyed from mucous patches on the operator's lips, by means of saliva used to moisten the needles or the pigment during the operation.

The last group of these cases of the non-venercal communication of syphilis relates *the operator acting as a medium*, conveying the poison from

one individual to another. In illustration of this, a large amount of material could be presented, but space permits of but brief mention of the principal facts.

Vaccination, as is well known, has on repeated occasions given opportunity for the transmission of syphilis, and need not be dwelt upon here. Hundreds of cases of this description are found in literature, and as an example may be mentioned the well-known epidemic at Rivalle, Italy, where 80 cases were reported, of whom 7 died.

Ritual circumcision has also occasionally been the means of syphilitic inoculation, the first reported cases occurring in 1805, since which time a considerable number of observers have reported instances of the same, and on one occasion—referred to by Jaffé⁹—thirty boys were infected by one operator in Vienna.

Transplantation of teeth—an old practice recently somewhat revived—has been the means of conveying syphilis, and skin-grafting has been followed with like result.

The operation of wet-cupping has repeatedly given rise to syphilitic contagion, the oldest account of this being in the case of the celebrated "Maladie de Brunn," in Moravia, in 1578. In this village no less than 80 persons were infected in three months by this means, in addition to about a hundred in the surrounding country. In Finland repeated epidemics have occurred from this cause, in one instance nearly two hundred persons being infected.

Cases have been reported where minor surgical operations, as opening abscesses, scarifying a hydrocele, the use of serres-fines after circumcision, etc., have given rise to chancres with syphilitic inoculation in the site of the wound, and injuries made by dental instruments have in like manner produced syphilitic infection. Razor wounds are also sometimes the site of syphilitic inoculation, possibly produced during shaving, possibly afterwards from other sources.

Eustachian catheterization has on repeated occasions been the means of conveying the syphilitic poison, no less than twenty-five persons reporting cases where this had occurred: of these cases about sixty were traced to the practice of a certain ear specialist in Paris, and some cases of the same nature have also been reported as occurring in this country. Surgical sounds and speculæ are also accredited with having produced like results.

From this very hasty and by no means complete sketch of the recorded methods and instances of the communication of syphilis in the various walks and occupations of life, it is readily seen that the disease may and does occupy an important position among those which can at any time affect the least suspecting, and that it is by no means always a venereal affection. It has been

⁶ Leloir: *Leçons sur la Syphilis*, Paris, 1886. P. 54.

⁷ Tep-ljaschin: Cited in Vertelj, *f. Derm. u. Syph.*, 1887, p. 1138.

⁸ Cited by de Beck. *Hard Chancres of the Eyelid and Conj.* Cincinnati, 1888. P. 48.

⁹ Jaffé: *Die Rituelle Circumcision* etc. Leipzig, 1886.

found to attack the young and the old, quite irrespective of sex and condition, and in all the instances alluded to quite independent of any venereal act or possibility. As each new case or series of cases comes to light, it becomes more and more probable that the number of instances in which syphilitic infection has thus innocently occurred is much greater than is commonly imagined. With a poison so virulent, and capable of being transported and introduced in so many different ways, and, as far as is known, endowed with the possibility of being preserved for an indefinite period, the only wonder is that cases of the non-venereal communication of syphilis are not even more frequent than they are now known to be.

The explanation is found in the nature of the virus, which requires a broken surface of skin or mucous membrane for its admission, and the application of the poison in sufficient quantity; when the conditions for its entrance are all present, inoculation rarely fails to take place on any and every portion of the body.

The reason why syphilis is so preëminently a venereal disease is found in the nature of the venereal act, the tender and delicate structure of the epithelial covering of the parts involved, and the frequent injury, together with the long period of comparative health during which the poison held in the system is capable of infecting others. When similar conditions are at all fulfilled in reference to other portions of the body and under similar circumstances, as in kissing, biting, and other modes of exposure, the contagion takes place equally readily and quite as certainly. Moreover, certain other diseases, as scabies, and the vegetable parasitic affections, are not infrequently communicated in sexual congress, and if this was had during the contagious period of such diseases as small-pox, scarlatina, and diphtheria, these would also be acquired, but in none of these cases would the term "venereal disease" be applied.

The thought here presented is that there is nothing in syphilis which makes it wholly, or necessarily, a venereal disease, nor which warrants the stigma which almost invariably attaches itself to the individual affected therewith. While the large majority of cases are undoubtedly acquired through venereal acts, there are also many cases, and we have seen that Fournier puts it at 25 per cent. in women, in whom the disease is innocently acquired. In some studies recently made I have collected the figures relating to about 4,000 distinct cases of extra-genital chancre in different locations, reported by various observers, a large share of which were non-venereal, and in a list of about one hundred epidemics of non-venereal syphilis which I have also tabulated, upwards of 3,000 victims were mentioned, in addition to indefinite statements where large numbers were alluded to. All this is quite exclusive of the

thousands of cases indefinitely referred to in literature, and the many scattered instances of innocent infection, where no record is made of the site of the chancre. Moreover, in all the accounts of syphilis where it has appeared, and even still exists endemically in many localities, as in the Radezyge of Norway, Sibbens of Scotland, Scherlievo of Dalmatia, and the syphilitic diseases of many countries, constant reference is made to its transference from one person to another by eating and drinking utensils, pipes, also by nursing, etc.

We come now to the most important part of the subject, namely, the prophylaxis of the disease. If, as we have seen, syphilis attacks the innocent in such a relatively considerable proportion of instances, and if every one who acquires the disease through venereal means becomes a focus from which syphilis may spread not only to the guilty but also to the most innocent and unsuspecting, it becomes the highest duty of all to curtail the amount of the disease present, and the ravages it may make, in every possible manner.

From what has preceded it may be readily understood, therefore, that syphilis is a disease which presents no little danger to the public health and to that of every individual. While undoubtedly an exaggerated idea of the perils connected with it could easily be obtained from the material presented in the preceding pages, it is impossible to shut the eyes to the fact that a measure of real danger exists, as is evidenced by the thousands of cases which have been in some manner referred to, where the disease has been acquired in a perfectly innocent manner. No amount of reasoning or argument can do away with the facts which have been quoted on the highest medical authorities, and the records of cases where the disease has been communicated innocently, not only in the daily intercourse and daily occupations of life, but also in the most varied relations; in the care of the sick and of children, in industrial pursuits, and in professional callings.

Syphilis is now one of the principal diseases which affect the human race, and undoubtedly is on the increase, owing to the utter want of all sanitary control over it in the larger part of the world. There are no data accessible to show its relative prevalence in different sections, except those relating to the armies of various nations; in many or most instances, however, even these returns are not available, inasmuch as they relate to "venereal diseases," and not to syphilis as a distinct malady.

In this country, I learn from the Surgeon-General's Office that there is no reliable information in regard to the prevalence of syphilis in the United States, there being not even any data furnished from our army. According to Sturgis,¹⁰ however, in the Army of the Department of the East, in

¹⁰ Sturgis, Relations of Syphilis to the Public Health. Trans., Am. Med. Ass'n, 1877.

the five years from 1870 to 1874, there were 1,488 cases of syphilis, or 4.22 cases per 100 men; in the Mercantile Marine of the United States, during 1872 and 1873, there were 3,779 cases of syphilis, or 15.33 per cent. of all patients treated. In the city of New York no less than 16.19 per cent. of all cases of sickness in the Mercantile Marine service was syphilitic. From data taken from a number of dispensaries and hospitals in New York City, during the year 1873, Dr. Sturgis estimates that the number of persons treated for syphilis during that year, in this city, cannot be far from 50,000.

Some idea of the frequency of syphilis throughout the country may be obtained from the statistics collected by the American Dermatological Association, from different cities in the United States, during the past ten years. It is here found that fully one-tenth of all cases reported by members of the Association were the different lesions of the skin caused by syphilis, it coming next to eczema in frequency. In some respects this presents, perhaps, one of the best means from which to form a judgment in regard to the comparative frequency of this malady, for as syphilis rarely fails to manifest itself on the skin at some period during its course, cases of this disease are more likely to be observed and studied in dermatological practice than in any other department of medicine. It is understood that the data referred to were collected from public and private dermatological practice, and not from venereal clinics.

It will be noticed that in our discussion of the subject very little reference has been made to syphilis as a venereal disease. From reasons which have abundantly appeared in the preceding pages it will be seen that syphilis is as a disease worthy of the utmost study, and from what is known of its various manifestations in the different organs of the body it stands second to none in pathological importance. The fact that in so large a share of cases syphilis happens to be communicated through sexual contact, and in so great a proportion of these it is from impure venereal relations, by no means warrants its relegation to a class of affections the mention of which is tabooed in good society.

While syphilis is a "venereal disease" in a certain sense, its prophylaxis by no means relates entirely to the restriction of venereal diseases, but must be placed upon the broader ground of the protection of the public health, and that of individuals, from a malady which affects the innocent and guilty alike, and which may come both when its dangers are anticipated and guarded against, and when they are least suspected.

In the matter of protection against syphilis, therefore, the subject of prostitution becomes a wholly secondary consideration, and the question is not one of "regulating prostitution," or of inspecting, licensing, or legalizing the "social

evil," or of protecting those engaged in it, but relates to the prevention of the unnecessary extension of a disease which certainly does produce a vast amount of sickness, misery and death.

That the spread of syphilis can be checked is self-evident, as has been conclusively proven by the fact that the large and small epidemics which have been mentioned have all been arrested when the cause has been recognized and sufficient measures have been introduced to prevent the further transference of the poison from one person to another. It is also abundantly shown in those instances where foreign governments have enforced stringent measures looking in this direction. We know certainly that the virus does not develop *de novo*, but that it is always communicated from one individual to another; we know, also, that within a certain period of time the disease ceases to be contagious or communicable, in each individual, so that if no new infection is introduced into a community, and those within it are guarded against communicating the disease until the contagion period has passed, the malady will cease to exist.

Such precautions are exercised, both by the public and by individuals, against other contagious diseases, small-pox, scarlatina, diphtheria, yellow fever, etc., and it is no more than proper that syphilis should be placed in the same category, and protection should be afforded against it, for it counts its victims by thousands, where other diseases count hundreds. The deaths ultimately caused by syphilis are now more than those from small-pox, while the injury to health, and the interference with life-work is much greater in the former than in the latter.

In regard to the means of prophylaxis against syphilis, these relate to the individual and to the public.

Individual prophylaxis will result from a more widespread knowledge on the part of the profession and the laity of the manifestations of syphilis, its dangers and the modes in which it may be communicated. In the history of all the epidemics of this disease, large and small, it is constantly stated that the true nature of the difficulty was not recognized, or that the dangers of infection were not known or appreciated even, until numbers were affected. As our knowledge of syphilis widens, and as the synthetic history of the disease is formed, so much less will be the danger of its communication by innocent means.

A glance at the clinical history of *syphilis insontium* as sketched in the preceding pages shows this very conclusively. For instance, the dangers of its communication by vaccination were never thought of until a considerable number of cases had been reported, and undoubtedly multitudes of others had occurred which were never known to the public; the inoculation by means of Eustachian catheterization was not suspected until many

cases had happened in the practice of a certain physician in Paris, in such a manner that the facts were indisputable; ritual circumcision had been practiced for centuries before it was demonstrated that syphilis could be communicated in the operation; and many other illustrations could be given.

Now, however, that these dangers are known and more or less widely recognized, we no longer have such events to record as are found in earlier years, and infection by lactation and other known methods is yearly becoming less frequent; in most countries such general outbreaks of syphilis as the *Maladies de Brun*, de St. Euphémie, de Chavanne-Lure, the *Pian de Nerac*, and the many other minor epidemics of the disease, are now well-nigh impossible.

But, on the other hand, it is not equally true that the innocent acquiring of syphilis is really becoming less frequent of late years, for with increased facilities of intercourse the opportunities for its propagation seem to be multiplied, and the actual number of instances of *syphilis insontium* seem to occur in larger proportion than formerly, as may be judged from the abundant records of such cases in current literature. Of course a certain measure of this apparent increase must be ascribed to the more accurate methods of recording in modern times, and the great facility of publication of the same. The present writer has personally recorded some sixty cases of extra-genital chancre, in addition to dozens, or rather hundreds, of cases of hereditary and marital syphilis innocently acquired.

The basis, therefore, upon which personal safety from syphilis must rest, has yet to be reached, for while the disease is allowed to spread unhindered by venereal contact, so long will cases of innocent syphilis continue to abound. This is evidenced by innumerable cases on record where the disease has been acquired both by necessary and unnecessary contact with those thus diseased. A single illustration may be mentioned, where a syphilitic man infected his wife, she then infected a woman who drew the breast, and through this latter woman ten others became infected with syphilis, several of whom died from the disease. How much further the malady spread was not recorded, but it is unlikely that it ended there.

Literature abounds in references to the medico-legal aspect of venereal diseases, and of syphilis in particular, and even a brief abstract of the subject would occupy much more space than can be given, while a transcription of the laws and enactments bearing thereon in other countries might occupy volumes. It is, indeed, a most difficult subject to handle, and one which has occupied the attention of many physicians and jurists, especially in France, Belgium and Germany, and it is in those countries that most efforts have been made by the Governments to stay the progress of the disease.

In Paris, as is known, there is a certain police inspection of public women, and statistics show¹¹ that from 1877 to 1881 between 800 and 1,200 women were each year sent to the prison hospital of St. Lazare with syphilis. The number of individuals who might be infected from these syphilitics can hardly be computed. In other cities in Europe there is also exercised a control over public characters infected with syphilis, and a varying amount of protection from the disease is thus afforded.

In England a reaction took place, as is well known, against the "Contagious Diseases Acts," and they were repealed some ten years ago, and no effort is now made there to control the development of syphilis.

In this country, as far as is known, there are no sanitary safeguards against the spread of syphilis, and there are very few hospital advantages for those thus affected, while in most of the cities of Europe there are large accommodations for this class of patients, amounting in Paris to between 1,000 and 2,000 beds. New York has but a relatively small service at Charity Hospital, while the vast majority of syphilitic patients are treated at the dispensaries, and are free to go about spreading the disease, often with lesions of a most dangerously infective character. It would be difficult to convey an idea of the carelessness and indifference of some of these patients when informed of the dangers attending their disease, and many, indeed, the far larger share of them, disappear from treatment long before they have ceased to be dangerous to others.

The republican ideas of this country would probably never endorse or submit to such sanitary police inspection and restraint as is exercised in certain European cities, but the question arises if there is not some way in which the end can be reached of arresting the spread of this dangerous disease? Can there be no safeguards thrown out which shall prevent its extension here as in certain countries in Europe, notably Russia, where whole communities have been syphilized, and Portugal, where the disease is almost universal?

The first step toward this, we believe, will be found in placing syphilis among other contagious diseases which come under the jurisdiction of the health officers, so that legitimate means can be devised and executed to check its spread, as in the case of other contagious diseases mentioned. The late Marion Sims¹² alluded to this subject in his address as President of the American Medical Association some years ago, using these words: "There can be no difference of opinion among us regarding the two following propositions: First, we want a system of sanitary inspection and control which

¹¹ Parent-Duchatelet. De la Prostit. dans la Ville de Paris, 1857, vol. ii, p. 305.

¹² Vibert. Nouveau Dict. de Méd. et de Chir. prat., vol. xxxiv, 1883, p. 916.

¹³ Sims. Transactions Amer. Med. Assoc., 1876.

will enable us to prevent the importation of syphilis from abroad; and second, we want a system of sanitary inspection and control which will enable us to take charge of the subjects of syphilis at home, and prevent them from spreading it through the community."

The profession is undoubtedly unanimous in regard to the desirability of having such a restraining influence upon syphilis as is indicated in the quotation given, and the only question which arises is as to the best method of carrying the same into effect.

If syphilis were first recognized as one of the great contagious diseases against which it is the duty of the Government to protect the community, the details of operation would probably follow in time, and as the public became aware of the dangers from the disease and the benefits accruing from its restriction, there would be no difficulty in securing proper laws relating to the subject.

It would be out of place here to present any detailed plan of operation, for the subject is of such vast magnitude and importance that it could not be compassed within the limits of this address, even if the writer were possessed of sufficient knowledge and judgment to formulate such a scheme. The suggestion, however, is most earnestly put forward that the time has certainly arrived when the evils resulting from syphilis should be fully recognized and the proper measures taken for its restriction. No longer looked upon as a purely venereal disease, it should be placed under the control of the proper health authorities, and it should be regarded quite as criminal to transmit syphilis knowingly as it is to communicate small-pox, scarlatina or diphtheria. It would then become the public duty of each and every one to guard against the malady, and its spread would be proportionately restricted. The hotel proprietor who knowingly allows one with small-pox to infect others, or who should not exercise due precautions after such a patient had occupied a bed or room, would receive punishment; and I take it that the keeper of a brothel would be subject to like punishment in regard to the careless spread of small-pox, scarlatina or diphtheria. If, now, syphilis were included with these maladies, something would be accomplished toward checking the extension of the disease. Such a person would then see that all the inmates of the house were free from syphilis and, again, would be very careful that no one entering the house should introduce the disease,

That a person may be held liable for communicating syphilis is abundantly shown by the many cases occurring in the literature of foreign countries. The works of Tardieu,¹⁴ Fournier,¹⁵ and others, are full of accounts of legal actions taken and fines and imprisonment inflicted for the wilful or

careless transmission of syphilis, and in some instances those actions were against physicians who had exercised precautions against the same.

How far the matter can be carried in regard to the restraint of syphilitics from exposing others cannot now be stated or even judged. Much enlightenment of the community is yet necessary in regard to the subject, and much thought will be requisite to determine exactly the best methods of controlling the slow but steady extension of the disease which is now taking place. These matters can safely be left for future consideration, after the first step has been taken in regard to placing syphilis among the other contagious diseases which are dangerous to the life and health of the Nation and of individuals. When syphilis is less frequent as a *venereal disease*, the cases of *non-venereal* or innocent syphilis will become proportionately rare.

EXPERT TESTIMONY AND MEDICAL EXPERTS.

Read before the Section on Medical Jurisprudence at the Thirtieth Annual Meeting of the American Medical Association, at Cincinnati, May 9, 1888.

BY ORPHEUS EVERTS, M.D.,
OF COLLEGE HILL, OHIO.

At the Hertford assizes (1699), in the trial of a man accused of murder, the prosecution—as stated by Mr. Justice Stephen, in his learned history of the criminal law of England—"collected a body of doctors to substantiate the proposition propounded by the crown." This case, says the historian, "supplies nearly the earliest instance of a trial depending largely upon the evidence of experts." It is further said, however, by the learned author—and the fact is significant if well considered—that "the defendant contradicted the evidence of the experts in a way that still shows any one who reads the case, that he was fighting with a perfectly idle superstition."

It is a fact conceded by English law-writers, and indicated by the asperity of medical writers towards them, that English judges have never held medical experts, especially in cases of insanity, in high estimation; while in this country the fact is patent to all interested observers, that the testimony of medical experts exercises but little influence in determining verdicts, when not in harmony with popular sentiments, or notions, respecting the merits of any given case.

In view of such facts, may it not be well to consider, briefly, the following questions, namely: What is "Expert Testimony?" What are its essential elements of value? Who are medical experts?

Expert testimony differs from ordinary, or non-professional, testimony in this respect, viz: Ordinary testimony consists of statements of facts as observed by the witness stating them,

¹⁴ Tardieu. *Étude Médico-legale*, etc. Paris, 1879.

¹⁵ Fournier. *Nourrices et Nourrissons Syph.* Paris, 1878.

and opinions based upon such facts, exclusively, the facts having been first fully stated. Expert testimony consists of opinions, based upon facts, as observed by the witness, or presented for his consideration hypothetically—having been observed by others—that he, by reason of peculiar knowledge, is, alone, supposed to be capable of interpreting.

This definition of expert testimony being accepted, it should not be difficult to determine the elements of value pertaining thereto. They are: *First*, Scientific principles generalized from facts, applicable and equal, to the solution of the problem under consideration; and *Second*, Capability on the part of the professed expert to make use of such principles in the solution of the problem given without bias or prevarication.

That scientific principles, applicable, and adequate, to the solution of the problem given, are essential to value, in the constitution of expert testimony, may be inferred from the fact, that without a knowledge of such principles, the testimony of one witness, of equal intelligence, and opportunities of knowing, would be equal in value to that of another. It is, also, apparent that such principles, to be applicable, and adequate, must bear a definite relation to the facts presented for interpretation, and present features of consistency, and accuracy, that admit of no alternative construction. Were it not so: if, for example, the principles of the science of numbers were not definitely related to the facts of accounting—or not so consistent and accurate as to justify perfect confidence in the prediction that two and two, if added, will make four, it would require no argument to convince us that the testimony of an "expert" accountant would be of no especial value, the data of his calculations being unworthy of trust. The same might be said of the expert surveyor, engineer, or astronomer—the value of whose interpretations of facts is derived from the infallible accuracy of the principles of the science of numbers. So, too, with the chemist (the value of his testimony as an expert depending, primarily, upon the accuracy of the principles of his science), if the relation of chemical phenomena to conditions of matter were not definite and uniform—given phenomena being inevitably sequential to given conditions of matter—the expert testimony of the chemist would be comparatively, if not entirely, worthless. Nor is argument needed to convince us that the testimony of the most capable expert, informed by principles of the most accurate science, might be vitiated, or invalidated, by dishonesty.

What, then, is the real value of medical expert testimony? And who should be considered as medical experts? Doctors of medicine are called upon to testify as experts in a range of cases involving questions of malpractice in medicine proper, surgery and obstetrics; and in cases of suspected crime

in which questions of cause of sudden, or unhistoric death arise; and in cases of still greater difficulty and importance, in which questions of mental conditions affecting the rights and privileges of citizens have to be adjudicated. Does that aggregation of knowledge known as "medicine" furnish the necessary principles for their qualifications as experts in all such cases? Are all persons engaged in the practice of medicine, and popularly recognized as "doctors," informed by such principles as do pertain to the so-called "medical sciences." These questions become especially pertinent in view of the fact that there is no recognized standard of educational attainment pre-requisite to either the title or privileges of a doctor of medicine in this country—and the common law admits them all to testify as experts—subject only to the test of cross-examination, as to qualifications, by attorneys who may, or may not, be capable of exposing false pretensions.

When we consider, seriously, the natural capabilities, and acquired knowledges, of a large proportion of the multitude of men and women engaged in the practice of medicine in this country, and the questionable character of much that is taught by the numerous "schools," or sects, of medicine, as science, these questions assume still greater importance; and the presumption of law that all are experts becomes preposterous. Even after eliminating from consideration all persons engaged in the practice of medicine, who are not graduates of reputable, regular, medical schools, the presumption would still be too violent for entertainment.

What, as a matter of fact, does such a presumption imply? Nothing less than an affirmation that the sciences constituting medicine, as taught in our schools, are informed by principles that are definite, comprehensive, and trustworthy beyond dissention; and that every one certified proficient in medicine, by such schools, is competent to make intelligent use of them in the formation of opinions as medical experts, on all subjects.

But to get at the grain that may be in this chaff, let it be admitted that the instruction given in our schools is adequate to qualify medical witnesses to determine, as experts, whether or not an infant found dead was still-born; whether or not certain wounds, seen or described, were necessarily fatal. Whether or not certain deformities following injuries were the results of malpractice. Whether or not, as indicated by symptoms, and post-mortem appearances, and chemical and microscopical examinations, in any given instance, death was effected by poison, etc.; still, the more important qualification of the medical expert to determine questions of mental manifestations, and human actions, whether or not influenced by pathological conditions of brains, or other organs, remains to be accounted for. What has medicine in its widest range of

instruction to offer on this subject? After all, how little! The most thorough-going anatomist is no wiser, respecting the genesis of mind, or the relation of mental phenomena to material conditions, because of his dissections. The most learned and practical chemist knows no more of such matters, because of his analyses, and syntheses, of inorganic and organized bodies, than does the anatomist. Therapeutics throw no light of principles upon the subject. Surgery is dumb, and obstetrics blind, respecting mental science. Physiology—that wonderful and growing science, that is to be, to all other natural sciences, what Aaron's rod was to the rods of the Egyptian magicians—has it not already furnished us with a new psychology, and is it not adequate to our present necessities? Let us see. If we depend upon science to furnish principles answering to our necessities, what are the requisites? It is requisite that such principles shall be applicable, accurate, and indisputable. Does physiology, as now taught in our schools supply the need?

Admit the fact that physiology has already swallowed up all the metaphysical psychologies, and that brains, with their appendages, the nerves, have come to be recognized as essential organs of mind, by which all mental operations are conducted. That when a man, or any other animal, feels, perceives, remembers, imagines, reasons, wills, or acts, it is because of material capabilities, and his brain and nerves do something. That there is a relation more or less definite, of mental capabilities, and characteristics, to size, form, and quality, of brain structures; and an association of certain mental phenomena with certain areas of brain substance. That modifications of mental capabilities and expressions, constituting all of the many degrees of capability, and peculiarities of expression, known as "idiocy," "imbecility," "mania," "melancholia," and "dementia," may be effected by arrest of cerebral development, and modifications of brain activities, whether effecting constructive or destructive results, and concomitant transmutation of energy—admit all this, as pertaining to present physiological knowledge—still the fact is apparent that we have not been supplied with such scientific principles as would, alone qualify medical experts to testify as such, in the jurisprudence of insanity.

Physiology, as taught in our schools, is indeed, still in doubt respecting the relation of mind to body: whether consciousness is an inherent quality of matter, manifested, as all other qualities are, by motion; or an attribute of a supernatural, indwelling spiritual being, not subject to sensuous observation, but inspiring or instigating, all bodily activities. In doubt, whether mental manifestations are concomitants of brain activities instigated by an immaterial ego, or the

inevitable sequentials of ever-changing conditions of brain-substance, influenced by environments.

Nor can physiology tell us, in accordance with any theory, just what the brain or body, or spirit, does when a man feels, thinks, or acts: nor just what instigates his activities, determines his movements, and differentiates his capabilities. So that, even with these doubts of physiology dispelled, and the subject of man's creation and constitution forever withdrawn from the shadows of superstition, and the overawing presence of the supernatural; and the science of psychology arranged in line with all other natural sciences, in accordance with a monistic theory of the universe—of which men are inseparable particles—we should still be unable to predict, with certainty, the phenomenal sequences of all given conditions of body, or brain, precedent; or to infer, with precision, conditions of body, or brain, by any given mental manifestations, unaided by other than physiological information.

Why then should doctors of medicine be regarded as experts in the jurisprudence of insanity, more than other persons of equal general intelligence? Is it not because of the fact that the official relation of the doctor of medicine to the afflicted, is now, as it ever has been, the most intricate, intimate, and privileged, known, or tolerated, by civilized or savage society; and because his movements as diagnostician, and dispenser of drugs with healing virtues are, to the uninitiated, within that same shadow of superstition that obscures their vision when trying to comprehend the mystery of thought, whether sane or insane? Hence, his greater opportunities of observation and study of the natural history of men and their disorders, and the endless variations of mental phenomena as related to material, observable, facts. Must not any claim of qualification as an expert in the jurisprudence of insanity, therefore, be based upon special, long-continued, intelligent, observation of the insane; and careful, comprehensive, studies of the natural history of insanity—rather than special knowledges derived from medical authorities—however advantageous such knowledges may be to the observer and student? And must not the value of the testimony of experts, so qualified, correspond to the natural capabilities, advantages of education, and experience, and general interest in the subject, of the persons testifying?

In these days, therefore, of specialties in medicine, and the habitual commitment of the insane to hospitals, or asylums, for treatment, or maintenance, at the earliest practicable moment, but few general practitioners of medicine have either the opportunity or disposition to so qualify themselves as experts, in this branch of medical jurisprudence; and but few—to the credit of the profession be it said—voluntarily appear in court pretending to be such.

Of the second essential element of value mentioned, the integrity, and freedom from bias, of the expert witness, but little need be said. Perverted knowledge is more dangerous than conceited ignorance. The natural tendency, of experts, however, is to invalidate their opinions more or less, by the admission of color derived, imperceptibly, it may be, from the interest taken in behalf of the parties employing them. Instigated, also, by professional pride, experts, like detectives, are more zealous in finding what they are supposed to be peculiarly qualified to find, than otherwise; a fact that in this country has been, so far as expert testimony has influenced courts or juries in any way, advantageous to defendants, in cases of criminal prosecution; and of plaintiffs, in cases of contested wills.

These are natural tendencies that experienced experts are capable of overcoming, when recognized; but should not be overlooked in estimating the value of expert testimony.

Of the mercenary and venal expert, nothing need be said. If such there be, they have no proper place in a profession so proverbially unselfish as that of medicine.

Cincinnati Sanitarium, May 4, 1888.

CONDITIONS THAT PRECEDE SERIOUS LESIONS OF THE KIDNEYS.

Read before the Mississippi Valley Medical Society, at St. Louis, Mo., September 26, 1888.

BY C. S. BOND, M.S., M.D.,

OF RICHMOND, IND.

The untiring energy of medical men of this period seems to be expended in a search for the primary causes of disease. At one time we awaited the inevitable result of some fatal malady to observe at the post-mortem its pathology. At a later period we were eagerly watching some distressed patient, slightly affected with disease, with the hope that some intercurrent trouble might destroy him, for the sake of a pathological specimen representing a less severe lesion. To-day we sincerely hope the patient will not die at all, however charming a knowledge might be brought to light by the legacy of his pathology. What we most desire as medical men now, is to avert the more serious lesions by recognizing the first departure from the healthy condition.

After the lungs are largely solidified or filled with purulent cavities it is of little avail to advise a trip to the mountains, or give drugs to bring about renewed health. There is a fearful mortality among such a class of patients; but as we are enabled to recognize the beginning stages, by better means of diagnosis and a more extended knowledge of the disease, we can act more promptly, and either check the malady in its initial stages or, what is better, prevent the patient from having it at all.

What is true of these lung lesions is equally true of serious chronic conditions of the kidneys. Francis Delafield, in his article on chronic parenchymatous nephritis in "Pepper's System of Medicine," speaks thus of the prognosis: "The prognosis of chronic parenchymatous nephritis is not good, but still it is not so bad as that of chronic diffuse nephritis; some of the cases recover and never have any further indications of kidney disease." Of chronic diffuse nephritis he says: "In every case of chronic diffuse nephritis, the natural course of the morbid changes in the kidney tissue is to become more marked and involve more and more of the kidney. . . . The disease is always a very serious one, and terminates regularly in destroying life, but the length of time that will elapse before this fatal termination, and the precise way in which death will take place, are difficult to determine beforehand."

As this is the most frequent form of kidney disease, it will be apparent that the mortality is very great, and if there is hope in the future of doing better work for this death-stricken class of sufferers who annually find premature graves, we must learn to diagnose this disease before the point now reached; before we are able to recognize the conditions by our present methods of diagnosis. When we find a patient suffering from swelling of the extremities and face, muscular twitchings, dyspnea, neuralgic pains in various parts of the body: a patient who passes albumen, with a diminished quantity of urine; who also passes casts and has a badly disturbed stomach, we are thus led to believe that such an one is beginning, or has begun sometime previous, the career of some serious lesion of the kidney; and our discovery is fraught with but little that can encourage the patient in cases of chronic changes in these organs.

For more than four years past I have been making examinations of urine from patients suspected of having some chronic lesion of the kidneys. The examinations have been conducted with an especial reference to the amount of urea excreted in twenty-four hours by individuals among this class of patients. Not only to cases of these diseases have the examinations extended, but also to other conditions of ill-health and to urine excreted by perfectly healthy individuals so far as I was able to judge. During this time I have made examinations for about eighty patients having the prominent symptoms laid down by the latest and best authorities as those denoting chronic structural changes in the kidneys. For these patients, extending over this space of time, I have a record of nearly 800 examinations, not including the other examinations just referred to relating to other diseases. During this time I have twice called the attention of the Indiana State Medical Society, through papers,¹ to this subject, and have

¹First paper, entitled "Urea" may be found in Transactions

received encouragement to extend this kind of investigation. I make mention of these observations in regard to urea not because I believe the subject to be an entirely new one, but because I want to call attention to some deductions later on, made from this series of cases, which I believe to be in line with our future knowledge on these subjects.

Many recent authorities have called to our notice the facts that in cases of serious kidney lesions urea is found in the blood in increased quantities, and that this in some way, when very excessive in amount, produces various nervous disturbances, even leading at times to complete coma; yet most of these same authorities have neglected to give us any very definite information concerning the normal quantity of this excrementitious matter which should be thrown off during twenty-four hours, or a knowledge of the amount of decrease in quantity in cases of diseased kidneys. The article by Dr. Delafield, before referred to, makes mention of the deleterious effects of urea when retained in the blood, but in diagnosing the cases he makes no statement concerning the amount of urea excreted in twenty-four hours.

In "Flint's Practice of Medicine" a more absolute statement is found. He says "that the daily quantity of urea is lessened," and in another place states that "it is of importance to estimate the amount of urea excreted daily, for which purpose it is of course necessary to determine the percentage of urea in the total quantity of urine passed in twenty-four hours. The specific gravity of a single specimen of urine is manifestly of no value in forming an idea as to the daily excretion of urea. It is necessary to take into consideration at the same time the quantity of urine voided in the twenty-four hours." While this is of value and corresponds to the latest observations on this subject, still he neglects to call attention to the quantity of urea he deems a lessened quantity, and in what prognostic value he would regard these different conditions; items which are vital in making a proper conclusion. Again, he does not state what should be the *continued daily* excretion of urea, in order that a comparison of these quantities might be made with former records, and with the daily course of the disease as manifested by the symptoms. Bartholow states "that urea is excreted in less than the normal quantity, and varies with the changes in the specific gravity of the urine." Loomis in his "Practice" says: "As the elimination of urea is steadily diminished, it is important to subject the urine to frequent quantitative analyses." This is said in regard to chronic parenchymatous nephritis. In speaking of the waxy kidney he states that "the amount of urea excreted is but little if at all diminished."

It will be seen, therefore, that so far as these authors are concerned, they make very indefinite statements in regard to the excretion of urea in these diseases, and they use this knowledge very little in making a diagnosis or prognosis in an individual case. I believe that what is true with regard to these authors is also, in a greater degree, true of the mass of practitioners. The urine is not examined with reference to the amount of urea excreted in twenty-four hours, and a careful record kept of the quantity for certain days during a long interval of time, so that a comparison can be made with the varying symptoms. That urea is retained in the blood of these patients is acknowledged by all who have given this subject a careful study, and that it produces serious nervous disturbances is also admitted, yet not a great deal of consideration has been given these truths in making up the diagnosis of these lesions. In my experience, retained, or diminished quantities of urea, is one of the constant conditions found in cases answering in all other respects to chronic diseases of the kidneys, and I have begun to regard of very little importance the presence or absence of casts and albumen, except as a differential diagnosis between the varieties of these diseased conditions. I should very much prefer to know that a patient passed constantly but 10 grams of urea daily, as a means of diagnosis, than to find that another case passed large or small quantities of albumen and casts, since by the former knowledge I would not only know the class of disease to which this symptom points, but I would also know something of the extent of the mischief then present in these organs, and could therefore be on my guard in regard to conditions pending. The healthy individual weighing 140 lbs., and living on a mixed diet, should pass between 25 and 35 grams of urea in twenty-four hours. Whereas a non-nitrogenous diet for several days might reduce the quantity of excreted urea to 10 or 12 grams in the same interval, or the failure to take food for several hours in sufficient quantity would lessen the amount excreted for the time; but neither of these conditions would be continuous, and if they were so, the other conditions indicating retained urea, as shown by the symptoms, would not be present; therefore a patient who passes from 10 to 15 grams of urea daily, for a long interval of time, and complies with the other conditions of health, can be said to have some structural changes present in the kidneys, or will, at a longer or shorter interval, have these organs diseased, if this quantity of excreted urea remains constant.

This brings me to the subject to which I most desire to call your attention in this paper, and to make it more plain, I have grouped all the cases contained in my record into three classes, all of which agree in that there is a constant diminished quantity of urea excreted in twenty-four hours,

and this quantity has remained below the normal for several weeks, months or even years, producing a class of symptoms which are also common to all three of the classes to a greater or less degree, while no evidence of any other structural changes could be detected by the most careful examination, except those common to this condition.

CLASS I. This class of patients pass a diminished quantity of urea, from 6 to 18 grams in twenty-four hours. Generally the urine is diminished, but may be greatly increased in quantity during this period. They complain of being exhausted upon the least exertion, also have dyspnoea, vertigo, nausea, and sometimes vomiting. Always complain of neuralgic pains in various regions of the body, generally more common in the intercostal nerves. They have twitchings of the various muscles of the body and œdema of the hands, face, and extremities which is more or less marked. Patients pass albumen and casts in large quantities, and nearly all, if not quite all of such on my list have death marked after their names, or are in a condition that soon will bring about that result. This sad ending is reached by a series of explosions which is attributed by the patient to taking cold, but which seems to be the tendency of the disease after it has reached such a degree of destruction to the renal organs and other tissues of the body. This class of patients is such as is described by authors under the head of chronic Bright's disease.

CLASS II.—This class, as the *first*, pass a diminished quantity of urea in the twenty-four hours with more of a fluctuation in the daily quantity, as shown by several examinations at short intervals, and although this tendency is toward the normal quantity, still very few arrive at this point, and fewer remain long in this condition when the record is still further extended. Patients pass but faint traces of albumen occasionally, with a few granular or epithelial casts, but more often neither albumen nor casts are found. This class of patients have neuralgic pains, vertigo, more or less disturbance of the stomach at times, with exhaustion on slight exertion.

Generally after a long time the *second* class fall into the *first*, as shown by examination of urine and symptoms. A few however pass into the *third* group and after a time even into a condition of apparent health. More of this group consult a physician, than those of the *first* class, for the first time, and something can be done for these patients if the disease is recognized at this point.

CLASS III.—This class comprises a number of patients who pass at longer or shorter intervals diminished quantities of urea in the twenty-four hours, the variation being from 10 to 20 grams, but this condition does not remain constant for repeated examinations, the tendency being gradually to approach the normal standard when properly managed. Still some of these patients pass

from this to the second, and even to the first class and at last die, and post-mortem reveals chronic interstitial nephritis. This class also complain of general weakness, pain in arms and chest, vertigo and general nervous disturbances. They pass no casts or albumen. They have but very slight, if any, œdema in any part of the body and there is almost always a relation existing between the symptoms and the amount of urea excreted. So much is this the case that knowing one you can predict the other, *i. e.*, if the patient excretes more urea the patient feels better and if, on the other hand, the symptoms are worse the excretion is less.

It will be seen that this division into three classes is arbitrary, and that the classes merge into each other in such a way as to have no natural division, and I shall here cite a few individual cases to make this classification more plain. These cases have been chosen because I believe them to be typical ones representing these classes, and are but few among a number that might have been given in each group of all the cases on record.

Henry M., German, age 40. Came to office in September, 1885, complaining of general weakness, headache, nausea, dizziness, shortness of breath, swelling of lower extremities. These symptoms had been more or less severe for several months. Examination showed slight traces of albumen. No casts. Diminished quantity of urine, and passed only 7.2 grams of urea in twenty-four hours. At this time the patient was laying brick and following his trade most of the time. Was eating fairly well of a mixed diet. Upon saline cathartics and digitalis patient seemed to improve for some months, but suddenly, while at work, again began having some of former symptoms and soon grew worse, and in a few weeks was dead. Post-mortem showed chronic interstitial nephritis.

Mrs. S., age 35. Came to office in October, 1884, complaining of dyspnoea, insomnia, vertigo, nausea, pain in intercostal region and headache. Was doing her own work in house. Was eating moderately of a mixed diet. Passed two pints of urine in twenty-four hours, but this contained but 10 grams of urea. Passed no albumen or casts. Repeated examinations at intervals of three or four days showed quantity of urea excreted to range from 10 to 15 grams in twenty-four hours. This condition lasted for ten or twelve months, when extremities began swelling. The dyspnoea increased, albumen and casts appeared in the urine and patient died with chronic interstitial nephritis, as in first class.

Simon M. Had, in April, 1886, pain on passing water. General weakness for several months previous. Pain in left side almost constantly. Passed two pints of urine in twenty-four hours, containing at first 9.6 grams of urea. Patient

presented no other evidence of disease upon careful examination. Passed no albumen or casts. Ate a mixed diet, and could come to office. Patient gradually improved upon saline cathartics, digitalis, and nitro-glycerine, until quantity of urea excreted equalled 28 grams in twenty-four hours, when all distressing symptoms were gone and has been apparently in good health since.

Miss Alice D., age 27. Came to office in April, 1886. Had been treated for uterine misplacement, persistent anæmia, and general nervousness, for several months previous, but gradually grew worse. Careful examination of uterus showed it to be in normal position and in a perfectly healthy condition. Patient was pale. Had headache almost constantly. Pain in lumbar region and limbs. Was very nervous and was gradually losing flesh. No other evidence of disease could be detected. The urine showed, sp. gr. 1010. Acid. Passed two pints in twenty-four hours, with no albumen or casts. Per cent. of urea $\frac{1}{100}$, or 6.7 grams, in twenty-four hours. At this time patient was eating fairly well of a mixed diet. Upon saline cathartics and nitro-glycerine patient gradually improved, as shown by symptoms and quantity of urea excreted, until November, 1886, when she was discharged apparently well and has so continued since.

Miss. P., age 20. Came to office in April, 1886, complaining of headache, dizziness and nausea. Feeling of general weakness. Pain in intercostal region. Chorea in right leg. Had been treated for these symptoms for several months previous but grew no better. Careful examination showed no other evidence of disease. Patient was eating moderately well of a mixed diet. Urine acid. Passed one and a quarter pints in twenty-four hours. No albumen or casts. Per cent. of urea $1\frac{1}{2}$, or 9 grams in twenty-four hours. Upon cathartics and nitro-glycerine patient gradually improved, until in one month she passed 17.2 grams of urea daily, and chorea and pains ceased, but still continued a feeling of general weakness, and she passed no more urea than the quantity named until November, 1886, when quantity reached 20 grams, where it has since remained, with slight variation, and patient is comfortable, but not well.

Another group of this third class of patients begin with the symptoms belonging in common with this class, and afterwards fall into the *second* and even into the *first* class, and die as befalls this class. These cases are cited, as I said above, in order that the general propositions might be made more clear, as well as to give an idea of the general course of treatment of the individual cases.

All these statements, drawn from a record of a number of cases, would seem to indicate that there are conditions which precede the more serious manifestations of chronic kidney lesions, that by a careful examination of the urine for the daily

quantity of urea, together with the symptoms, might be discovered long before the more hopeless symptoms that we now recognize as those of Bright's disease, are manifest. I believe, still further, that in view of these facts it must be admitted that there are changes taking place in the system at large which are in common with the conditions present in the kidneys, that interfere not only with excretion, but with general nutrition, and in some way produce at first irritation and afterwards more or less extensive chronic inflammatory results in various tissues of the body. As still further proof of this proposition it is only necessary to call attention to many inflammations which accompany serious lesions of the kidney, which originate often in the early stages of the diseased condition, and as I said before, I do not believe they are associated as cause and effect. It is a frequently observed fact that retinitis accompanies these diseased kidneys and is generally looked upon as secondary to the more serious kidney lesions, but retinitis has been often discovered in the earliest stages of kidney disease, and has even been pointed out as a forerunner of these conditions. Endocarditis, pericarditis, pleurisy, and other inflammations of serous membranes may also be reckoned as a part of these general disturbances, and a careful examination of the urine will disclose, even before the outbreak of these diseases, an abnormally small quantity of urea excreted by patients answering in all other respects to the conditions laid down above.

The point of departure from the healthy condition in the development of this class of patients is not well defined, but it is safe to say that it is either to be found in the vaso-motor and trophic disturbances due to an accumulation of urea in the blood, or these disturbances cause an interference with the normal excretion, and are then followed by this secondary irritation due to the presence of an abnormally large quantity of urea. It is the purpose of this paper, however, simply to show that at an early stage of these diseases a diminished quantity of urea is excreted in twenty-four hours, and that many of the symptoms at this early period are identical with those found in the well recognized cases of chronic kidney lesions. That this diminished quantity of urea can be made a factor in diagnosis long before albumen and casts occur in the urine, when the patient is going from one doctor to another, being treated for uterine disease, anæmia, dyspepsia, general debility, and nervous exhaustion. That it is the duty of every doctor to make examination of the urine for urea in cases presenting one or more of the prominent symptoms before mentioned in this paper, and to give such treatment as is well known to have the power to eliminate this irritating substance from the blood.

In conclusion, I believe firmly, that if doctors will give careful attention to these examinations

they will be able to recognize a very fatal malady in the infancy of its career, when there is hope of checking it before it reaches that almost hopeless condition now known as Bright's disease, and that you will be surprised many times to find that cases which you, or other doctors, had been treating for other diseases, pass after careful examinations and treatment into the second and third of these classes, and will by proper attention get still better, and after a time entirely recover. On the other hand, you will be equally surprised to find that patients you had been treating for dyspepsia, anæmia, or nervous prostration, will begin to pass albumen and casts, and be horrified at the knowledge that your patient has at last chronic Bright's disease.

THE EDUCATION OF THE DENTIST, YESTERDAY, TO-DAY AND TO- MORROW.

Read at the Joint Meeting of the American Dental Association and the Southern Dental Association, at Louisville, Ky., Aug. 29, 1888.

BY D. R. STUBBLEFIELD, A.M., M.D., D.D.S.,
OF NASHVILLE, TENN.

It does not require a Methuselah to look back to the birthday of Dentistry. She has made such rapid strides forward among the sciences, that, though comparatively young, she demands and receives recognition at the hands of the most erudite. Her ranks are filled by all kinds and nationalities of men, who have all varying degrees of natural fitness. But there was a time when this Cosmopolitan condition did not exist. Then the field was new, and filled almost entirely by uneducated men. There were, however, a few daring souls, who appreciated its importance and who felt an impulsive urging from within of a bias for its special duties and demands. They were the self-elected leaders of a forlorn hope, as it were, and did not expect much but hard work and poor appreciation of their services. But like Gideon's little band, they were filled with that indomitable determination to succeed that almost always wins the battle, tunnels the mountain, or gains the victory of any kind. Conversely to a survival of the fittest, they were the fittest, volunteering themselves to do or die in a chosen life-work.

The point I mean to make, is, that each candidate for the then questionable honor of being a dentist was, by reason of his self-election, generally equipped with a special aptitude for dentistry. There were exceptions to this general rule, doubtless, but they were only sufficient to prove the rule, not invalidate it. The outcome was so uncertain that each applicant for the then questionable honor, determined his fitness by a thorough investigation of his own powers, and then fully consecrated himself to his work. Each

filled his own proper niche in life. Each had a single purpose and was devoted to his cause. Each was willing to work in the very face of poor opportunities to learn, and poorer facilities with which to work. It was by dint of effort often repeated, and against failure as constantly recurring that success was at any time to be achieved. General education was rare, not the rule. Professional generosity was not born, and narrow-minded jealousy stood ready to kill the inquisitive learner. And it was not strange that each was so niggard with his hard-earned store, when we remember the daylight was not broad, but only the dawn threw its uncertain beams upon them. Our Pilgrim Fathers constantly carried their arms against the ever possible attacks of the destroyers; so, these, our professional fathers, guarded their small secrets and jealously kept them against the treachery of others, as they understood it. To be sure, it is not our way, but the customs of that day and this differs widely, and the sun of professional generosity had not dispelled the mists and fogs of ignorance that still obscured the landscape. In the light of the present they appear almost contemptible, and would be so, but for the extenuation, found easily in their different surroundings, which puts them within the pale of a generous charity. Let him, who would have been better under the circumstances that enthralled them, cast the first stone. I do not condone the fault, but I demand, a fair and right, considerate, not to say lenient, judgment for the doers.

And yet they need no defender. They did too much, in the very face of confessed disadvantages, to make the foundation upon which we of to-day stand, for us to deny them credit, or refuse to be grateful. The perfection of an invention is certainly very commendable, but while we honor the perfecter, we must not lose sight of him who conceived the idea from which it grew. Those honest-hearted ones held firmly to their convictions, and dared to promulgate them with their whole lives. They irresistibly command our respect. The world in its ignorance denied the necessity for their work and refused, except from the direst need, to allow them a chance to prove its value. Against the tide of these and all other opposition they urged the bark of dentistry into the haven of respectable recognition. It was a struggle, in effect, like that of the Colonies for Independence, against Tory doctors within the scientific world, and all the opposition from without combined. We have much for which to thank these foundation builders of the past, and we would be recreant to all professional heredity to refuse it. They developed appliances; we use them. They founded colleges of special learning; we are the learners. They questioned all methods and put infinite pains upon each; we are easily able to select the best for each case. They were

the garnerers; we the feeders that live upon their grain. Thus in all things the planters of yesterday feed the open mouths of to-day.

The dentists of to-day are the legitimate result of their determined adherence to principle. We stand so nearly related to them that we are necessarily the objects of their benefactions. We deserve no special credit for being even better than those of yesterday, for we can easily obtain the benefit of their work without a tithe of their labor. The sun of scientific enlightenment has revealed the fact, now fully recognized and conceded by the scoffers of the past, that dental science is necessary to the world, and the profession itself is just as reputable as any of the so-called "learned ones"—that is, in fact, one of the learned ones. The world admits that dentistry is a branch of the general healing art, without reference to its being or not being a specialty of medicine, and as such is entitled to all consideration. I cheerfully give the meed of praise to the dentist of yesterday, who, as he was in many instances uneducated, suffered from a narrow view, yet who carried within him the sign-manual of the Creator, manifesting itself in a special aptitude for the work. We, of to-day, do not flatter ourselves unduly by claiming that, with like careful selection, and better facilities for preparation, we can show greater advancement. But there is a trouble engrafted on us as a body professional, the consideration of which brings us to consider the dentist of to-morrow, namely, that the painstaking, introspective, self-examination, is not practiced in the selection of dentistry as one's life-work, as it was formerly done. It is too often the case that the idea of great emolument (?) proves the allurements, and the question of natural fitness is not even considered, much less settled. In other words, too many men are dentists (so-called at least) without self-election, in the sense of being naturally fitted for the work. One becomes a dentist because his father was a dentist, and he loses sight of the fact that heredity has stamped him his *mother's* boy; another becomes a dentist because a boy friend, who is unusually well fitted for it, is succeeding, although he may be entirely incomparable to his friend.

Dentistry now on a plane with other professions, must expect to suffer like them from the entrance of ill-advised votaries, enticed by adventitious inducements. It is an irrefutable fact that men are to-day forging ahead in the professional world by dint of main strength, where pride and intelligence are backed by fair cultivation, who would evince the grandest human ability in other vocations. It is a pity that inherent power should be misapplied. This could not always be prevented, but judicious selection, based upon mature consideration of character, should be the highest duty of parents. The pride to be this,

that, or the other, developed prematurely in a child, should be most sedulously avoided. Too much care can not be expended to ascertain the trend of the composite inheritance of a child. Pride of station and ancestry should be overcome in the all-important selection of a thoroughly congenial and compatible life-work. The most earnest scrutiny should be kept upon the formative forces bearing upon the child, so that they are not allowed to prove deformative processes, to warp a splendid success into as splendid a failure. The children of any profession are the natural recipients of any hereditary qualification for that profession, but we must not lose sight of the fact that the flow of hereditary is deflected and often changed entirely by the other side of the family. Hence, no invariable rule can be set to govern people who are not invariable. All of Phrenology may not be true, but enough to prove its general truth is found in human faces, built upon substantially the same anatomical bases and with parts that differ but slightly, and yet how different! None can doubt that different men have different qualities of mind as well as different faces, and that, therefore, they are better fitted to pursue some profession than any profession, to advantage. And yet, there is a general intelligence that enables some to follow almost any profession with credit, when faithful application is made. Such men may be thrown out of the channel best suited to them, and, still, against a natural bent, they develop success out of failure. None will dare to deny, however, that they would have done more, gone higher, or reflected greater luster on themselves in that calling that satisfied their whole nature than the work in which they had been perfunctorily engaged. If this is true, then the special work of dentistry offers the best field for some of the diverse minds of the world.

These very ones I commend, out of which to make the dentists of to-morrow. They are Heaven-elected dentists, if they properly qualify themselves to discharge its obligations.

The profession should demand three things to be done, one by them, one by itself and one by the schools. *First*, demand that a broad foundation of primary education should be laid, as preliminary to all other intellectual preparation. I go back of professional training in this and demand the same educational qualifications that the most learned profession ever demands. To prepare for law, they search all fields of educational lore, drink at all fountains of knowledge, and then put on a capstone of law. Just such a course, I claim, is best, if not always possible, for a dental student, and even more important, since the issue of life and death is, at times, in his hands. More is demanded of the studenthood to-day in all branches than ever before, and dental students must expect exactions commensurate with any other. Minds trained primarily and cultivated

persons, added to that trend of character that is the natural qualification, should be considered the *sine qua non* for correctly prepared dental students. Trained minds, that they may bring skillful intelligence to work out the conceptions of our high and progressive science; and cultivated persons, because our intimate personal associations demand that we be agreeable in necessarily painful duties. Such only would rise to the highest conceptions of our future. The beginners are on an average too crude from which to obtain the best results. They deem themselves well qualified to meet all requirements, when they decide to honor our profession with their patronage. The will is essential, but not all-sufficient. The day has come when better methods must prevail. Years ago, it was excusable to commence the study of dentistry without a proper foundation, but I insist that such a course is not up to the requirements of the times. A log cabin or a wigwam might be built upon the level earth, but a Washington Monument, or a Liberty Enlightening the World, must have a deeply laid and a well constructed foundation. Dentistry of to-morrow must over-top dentistry of to-day, and the basis must be deepened and broadened as the top goes upward. To do this the profession must awake to its responsibility and actively demand of our dental schools that they shall be more exacting as to a suitable preliminary education of their matriculates, and that they shall provide the means necessary and demand of their students a broader and more thorough knowledge of the fundamental sciences of medicine and surgery, before graduating them as Doctors of Dental Surgery.

Second, one by itself, and that is to establish a higher, better moral tone. The old idea that what was good enough for my father is good enough for me, must be supplanted by a more progressive, a more enlightened view of our calling, and the essential factors that constitute its higher standard. Such a revolution can not be accomplished in a day. Harvest is always preceded by a preparation and proper seeding, and a long time of patient waiting. But it ought to be done, it must be done, if we intend to rise with the tide of the general progress of the hour. Each dentist must become a radiant center of elevated moral tone, be the circle that surrounds him great or small.

Third, one by the schools, which must assist by a sensible elevation of the standard for entrance, a judicious extension of curriculum, and a more rigid demand for thoroughness before conferring degrees. Cast iron regulations can not avail, because the modifications at any point are not identical or comparable to those at any other point. Ends must be aimed at; means will take care of themselves. Let the sentiment be unanimous and utterances conform to it. The moral backing

thus developed will engender courage to begin the revolution. Be assured, it can not be wrought by chance, and indifference will result in forging more indissolubly the fetters that bind us to the traditions of our past. Schools can not do more than reflect the impress of the profession in the aggregate, as seen upon the collected pupils from all sides. Let every dentist constitute himself a committee of one to properly prepare one student. The great rolling river is just what its tributary springs make it, and dentistry will be elevated or depressed by your efforts and mine. It behoves us to rise to the emergency and do our best to discharge the obligation that we assumed in the marriage vows of our high calling. It is unquestionably essential that the schools shall be more thorough, but our duty lies back of their work. We have one responsibility and we must act, we must work, or die out of the way of those who will.

MEDICAL PROGRESS.

EFFECT OF COFFEE ON THE URINE.—DR. DUMONT, of Louvain, has undertaken a series of researches on the effect of coffee drinking on the urine, from which it appears that, though the diurnal quantity of urine is not seriously interfered with, the composition undergoes a very decided change. Dr. Dumont kept the subjects of his researches for some days on ordinary diet, the constituents of which were determined. During part of the time only was coffee added, the quantity being three cups—corresponding to about two ounces of roasted coffee—per diem. By regular and careful analyses of the urine, it was found that during the days when coffee was taken the urea passed was increased by about seventy-five grains. The effect on the urea was produced immediately the coffee was commenced, and as soon as it was omitted the quantity of urea returned to that which it had exhibited previously.—*Lancet*, Sept. 29, 1888.

ARSENIC IN RHEUMATOID ARTHRITIS.—DR. WILLIAM OSLER recommends Fowler's solution in initial doses of five drops three times a day in the treatment of rheumatoid arthritis. This dose is gradually increased to the limit of tolerance and then held there, the effects of the drug being carefully watched.—*Medical Record*, November 24, 1888.

ANTIPYRIN IN LARYNGISMUS STRIDULUS.—MR. MONTAGU PERCIVAL, of Waratah, Tasmania, reports successful results in 24 cases of laryngismus stridulus treated with doses of from 2 to 5 grains of antipyrin every hour. The cases were due to sudden changes of temperature, with damp winds.

Address

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 68 WABASH AVE.,
CHICAGO, ILLINOIS.

All members of the Association should send their Annual *Dues* to the *Treasurer*, Richard J. Dunglison, M.D., Lock Box 1274, Philadelphia, Pa.

LONDON OFFICE, 57 AND 59 LUDGATE HILL.

SATURDAY, DECEMBER 22, 1888.

"PENNY WISE, POUND FOOLISH."

We hasten to endorse the Peoria *Transcript's* proposition that the general assembly promptly abolish the State Board of Health. Founded originally for the promotion of the sanitary condition of the people it has lapsed into a mere technicality of medical practice and a mutual protective society for the profession of Illinois. No valid objections could be advanced against the Board of Health being operated in the interest of the medical profession if it were not maintained at the expense of the tax-payers. The cities are governed by sanitary regulations of their own, while in the country districts any justice of the peace is empowered to act in behalf of the protection of public health. The Board of Health seems to be an unnecessary institution and one from which the people derive little if any benefit. As its maintenance is quite expensive it should be altogether abolished in the interest of economy.—*Bloomington (Ill.) Eye*.

Were Cicero living at the present day he would not have to go far to find journalistic Catalines to whom he could say: *Quosque tandem abutere nostra patientia, O Catalina!* The *Bloomington Eye* is sadly in need of a pair of spectacles with which to read the act of Legislature creating the Illinois State Board of Health, and that will enable it to see what the Board has done and is doing. The Board was created for two objects: 1. To promote and take care of the sanitary condition of the State of Illinois. 2. To regulate medical practice in the State.

It has been but a few months since we showed (THE JOURNAL, June 9, 1888, p. 719-720) that the tax-payers of Illinois are fully reimbursed for all the expenses of the State Board of Health by what the Board saves to the State in its sanitary

work; that in one instance, the small-pox epidemic of 1880-82, the Board caused a saving, outside of Chicago, of 1,517 cases, 320 lives, and more than \$2,790,000 (exclusive of actual life-value). Dr. Farr estimated each life as worth \$795 to the State; so that the saving in life value was \$254,400; and we thus have a total of \$3,044,400 saved by *sanitary work* at one time, not to speak of what has been done since 1882. In regard to the regulation of medical practice, careful estimates show that since the Board has practically cleared the State of itinerants, quacks, and charlatans, two years ago, \$450,000 have been saved to the people of the State.

We may say, then, that the case stands as though the State Board of Health had deposited with the State Treasurer \$3,494,400, from which to draw interest for its maintenance. At a rate of interest of 3 per cent. this would give the Board \$104,832 annually, which amount, we may remark, the Board is *not* spending. The expenditure of the Board from the State Treasury for the fiscal year ended September 30, 1888, was the small sum of \$8,559.25. The State Railway Commission spends more than this and does far less work. If the *Bloomington Eye* cannot see this we would advise it to consult an oculist and an arithmetic. If the people of Illinois are unwilling to pay less than 3 per cent. on all moneys actually saved to them, they have not the business tact and foresight for which we give them credit. The house to house inspection and State sanitary survey, which have been carried on since 1884, have done a great deal towards preventing disease and reducing the death-rate of the State. If anyone can make out a balance in favor of the medical profession on account of a board of health, we shall be glad to see how it is made. How much money was put into the pockets of the physicians of Illinois when the State Board prevented 1,517 cases of small-pox?

In the yellow fever epidemic of 1878-79, the action of the Board saved thousands of dollars to the State; and with the Sanitary Council of the Mississippi Valley it has done a great deal in keeping yellow fever out of this section. It has done efficient work in preventing the introduction of cholera into the country. Since the organization of the Board epidemics of scarlet fever, diphtheria and typhoid fever have been less prevalent, and when outbreaks of these dis-

eases have occurred, they have been limited, to a great extent, through the Preventable Disease circulars of the Board. It is but a few months since the Secretary of the Board refused to quarantine against yellow fever refugees at Cairo, when quarantine would have been wholly unnecessary, and thus saved thousands of dollars to the Contingent Fund of the Board, and from \$50,000 to \$100,000 to the business interests of the State. The Illinois State Board of Health has also been active in securing the coöperation of the various State Health authorities in preventing the introduction and spread of the various epidemic diseases.

Admitting for a moment that one of the functions of the State Board of Health is that of "a mutual protective society for the profession of Illinois," we may ask if certain facts do not justify State protection of the profession. Is there any other profession that gives its time, skill, and services so freely, and so gratuitously to the people of the State, as the medical profession? Who gives gratuitous service to the poor man, in and out of the hospital, newspaper editors or doctors? Who is most frequently robbed of just earnings, the merchant or the doctor? Who gives gratuitous advice most frequently, thus cutting off his own income, the lawyer or the physician? When an epidemic is raging, who so often gives time, health, and even life to aid the sufferers and stay the disease, as the doctor? Can the editor of the *Peoria Transcript* and *Bloomington Eye*, tell us of a legal dispensary, to which people go for free advice when they are well able to pay for it? Can they tell us of a clothing, a food, a fuel dispensary to which dishonest, well-to-do people go under the guise of objects of charity and obtain relief for which they are fully able to pay?

The suggestion that "any justice of the peace is empowered to act in behalf of the protection of public health," is one that no one in full possession of the common mental powers of the human being would make. Why not leave health matters to the shoemaker, the coalheaver, or the editor of the country paper? Either one knows as much about health matters as the justice of the peace. And why not give over the entire management of the asylums for the insane to the County Clerks, the State Railway Commission to plumbers, and the financial manage-

ment of the State to the Sheriff of Sangamon County?

After all, it is not difficult to account for such expressions of irresponsible opinion as those quoted. The State Board of Health, by driving itinerant quacks and Indian doctors from the State, has reduced the income from advertisements of some of the newspapers. *Hinc illa lachryma.*

SANITARY INFORMATION BY COMPARISON.

DR. HORLBECK, of Charleston, has recently visited several of the large Northern cities gathering data for a report to the Charleston Board of Health on the sanitary system of the city. This method of obtaining information in regard to health and sanitary matters is certainly to be commended, as likely to be much more productive of good results than information acquired from books and printed reports. And since, according to the recent reports of the Registrar-General of Great Britain, there has been so much improvement of late years in the sanitary condition of Great Britain, notwithstanding the crowded condition of the population, it is very probable that it would be productive of good results if some of our health officers would pay an occasional visit to the Victorian Kingdom, and see how it is kept in such a healthy condition.

Not to speak of the many matters, methods, and institutions of sanitary interest that may be found on the Continent of Europe, it is not too much to say that any State would be largely the gainer that would send an intelligent health officer on a one year's commission to England and Scotland to study their sanitary institutions and methods. At this distance we are likely to think that a visit to one or two cities would be sufficient. Such is far from being the case. One can find something new and interesting in sanitation in almost every city of Great Britain. The sanitary methods of Edinburgh differ from those of Liverpool, and those of Liverpool from those of Manchester. The sewage farms of Edinburgh could be compared with those of a few other places in Great Britain, and these with those of Berlin. The end is the same—the prevention of disease and reduction of death-rate; but the means by which the end is attained are often essentially different. Actual knowledge, gained by actual see-

ing and experience is always more valuable than that gained from reading.

The proof of what we say may be found in the enormous strides in the management of asylums for the insane, due in great part to actual comparison of methods in various institutions in all parts of the world. One or two thousand dollars, or even more, spent in such comparisons and observations, might be the means of saving fifty times the amount to a State or City in less than five years. The amount of money spent in this country, annually, upon useless experiments, because of ignorance of what has been done, and of ignorance of suitable methods and conditions for certain places. At best, health officers have far too little practical preliminary training, which is certainly as necessary for their efficiency as is hospital practice for medical students before they enter upon private practice.

EDITORIAL NOTES.

OPIUM SMUGGLING ON OUR NORTHERN BORDER.—A few days since a wagon loaded with 800 pounds of crude opium was seized and the driver arrested by United States Revenue Officers on the Dakota line west of St. Vincent. About the same time 476 pounds, prepared for smoking and packed in boxes, were seized at Denver. The boxes had been sent from St. Paul, marked "household goods" and consigned to A. Neilson, who was also arrested. Another large amount, valued at about \$20,000, was found by Customs Officers in a shanty near Port Hope, where it had been landed by a schooner from Sarnia, Ont. The man in charge of the opium in the shanty made his escape. These several seizures, added to the recent developments with which our readers are familiar, render it quite certain that an extensive and well organized system of opium smuggling has been carried on for some time through the British possessions and over our border at various points. The knowledge now in possession of the United States revenue officers will probably enable them to break up the illicit trade, and punish, at least, some of the chief offenders.

WATER-SUPPLY OF JERSEY CITY.—Sixty physicians in Jersey City have signed a report to the Board of Works, saying that the water of the city is good enough to drink. The Passaic River re-

ceives the sewage and street washings of Paterson, N. J., the sewage and drainage of Pompton and Passaic City, it is said, and the offal from slaughter houses, the waste from factories, and the drainage from the dwellings along the river. Several chemists have found the water of the Passaic River contaminated by sewage. The physicians of Newark (supplied with the same water) assert that the water-supply of that city is impure. The Croton water is much better than that supplied to Jersey City, and yet Drs. John C. Peters and Cyrus Edson say it is far too impure for New York. As a matter of fact, it would be far better if physicians were to trust to expert analyses rather than to personal opinions, possibly not well founded. No water is good enough to drink if it can be made better.

AN INCOMPETENT AND USELESS OFFICER is the present Coroner of San Francisco, if he may be judged out of his own mouth. The City Physician of San Francisco has recently resigned, and his letter of resignation was uncomplimentary to the Sheriff and Coroner. The Coroner stated at the meeting of the Board of Health that time and time again he had shielded the City Physician "to prevent the too evident fact of his incompetency from showing itself to the public." If the Coroner spoke the truth he is an unfaithful officer; if he did not speak the truth he is equally unworthy of confidence. In either case the city would probably be the gainer were he to resign. At best, the sooner the non-medical coroner becomes a thing of the past, the better for all concerned.

SANITATION IN INDIA.—During the 20 years ending 1885, says Surgeon-General G. Bidie, the deaths from small-pox in India averaged over 33,000 per annum, and for every death about 10 persons had the disease and suffered mutilation. In the Madras Presidency the four great destroyers of human life are cholera, small-pox, fever and bowel complaints, the average number of deaths from these diseases alone being about 339,000 every year. In the 50 years ending 1886, the total losses to England, France, Germany, and Austria on battle-fields amounted to but 386,000, against the annual 339,000 of the Madras Presidency from disease. The country is studded by towns and villages that have been rendered terribly foul by the filth of centuries.

DR. H. G. WILDMAN, of the firm Wildman and McCoy, of this city, whose license to practice medicine had been revoked by the Illinois State Board of Health on account of alleged unprofessional practices, took an appeal to the Governor of the State, who has now reversed the decision of the State Board. Would it not be a benefit to all parties to have the Chicago Medico-Legal Society, composed of intelligent medical and legal gentlemen, fully discuss and endeavor to define the proper powers and duties of the State Board under the State law for regulating the practice of medicine? Does the Board possess both legislative and judicial powers, or neither?

DISEASED MEAT AS FOOD.—The State Board of Health of New York recently received a communication from Monroe, N. Y., to the effect that pleuro-pneumonia had broken out among the cattle there, and that 150 cattle had been killed. The local health officer asked whether the cattle so killed should be allowed to go on the market as beef. An emphatic negative answer was returned to this part of the dispatch, and the officer was directed to prevent any such use of the carcasses. It is a commentary on modern methods of educating the people that health officers need ask such questions.

LARYNGOTOMY ON A HORSE.—Dr. S. W. B. Werntz, a veterinary surgeon of Philadelphia, recently performed laryngotomy on a valuable horse, for the condition known as "weazing." After the wound was closed the horse took food and water without difficulty, and at last accounts seemed to be doing well.

A NURSE'S HOME has been opened in Philadelphia, having been established by the managers of the Pennsylvania Hospital. The Home affords accommodations for twenty-five nurses. The rooms are well fitted up, and the nucleus of a library has been formed.

AN ANATOMICAL SOCIETY has been organized by the students of the University of Maryland, Dr. J. EDWIN MICHAEL being the President. The University Museum is the place of meeting and study.

DR. J. B. BOWEN, a prominent physician of Bridgeton, N. J., died on Dec. 12. He was 50 years of age, and was graduated from the University of Pennsylvania in 1861.

SOCIETY PROCEEDINGS.

Gynecological Society of Boston.

Regular Meeting, May 10, 1888.

THE PRESIDENT, HORACE C. WHITE, M.D., IN THE CHAIR.

DR. SAMUEL N. NELSON exhibited

AN EXTRA-UTERINE FŒTATION,

and the pelvic organs of a patient who had died from abdominal hæmorrhage due to rupture of the sac. On opening the abdominal cavity at the autopsy it was found to be filled with clotted blood intermingled with the coils of intestine. In the right iliac region was the ruptured sac from which the blood had escaped. This was found on dissection and removal to have originated in the fimbriated extremity of the right Fallopian tube. The sac was about 2½ inches in diameter, and contained a fetus about 4 inches long. The uterus was enlarged, the cavity measuring 4 inches, and the anterior wall on section showing a thickness of 1 inch, including a well marked decidua, which was ¼ inch in thickness. The left ovary and tube were normal.

DR. HENRY O. MARCY: The history of the case from which was removed the specimen just shown was very interesting. Mrs. X., æt. about 35 years, was rather fleshy, with thick abdominal walls. She was the mother of seven children, but had not been pregnant for seven years, since which time her menses had been irregular. The patient suffered from indefinite abdominal pains with nausea, with sensation of sinking at the stomach. There was a slight uterine flow which, for the most part, confined her to the bed for four weeks prior to death. During this time she steadily lost flesh and strength. The breasts were soft and flaccid. The abdomen was slightly tender on pressure. The uterus was somewhat enlarged and slightly retroverted, but easily movable. There was no enlargement to be felt about the uterus by the most careful examination, and extra-uterine fœtation was dismissed from the discussion. She had seemed gradually to improve until the night before death, when she was seized with most excruciating pains resulting in collapse. She was seen by Dr. Nelson and me a little before her death. The cause of the extreme condition at that time was plainly to be attributed to hæmorrhage within the abdominal cavity from unknown cause.

DR. LEVI F. WARNER: In these cases there is generally nothing that calls to the mind of the physician the real condition of things. Usually they are not suspected. Once Dr. Hitchcock did suspect the condition, and he saved the patient's life by having everything in readiness for opera-

tion. In a certain case coming to my knowledge the doctor aspirated and withdrew 2 ozs. of fresh blood, and it was called an hæmatocele by an expert. The aspiration was continued until the woman died. Here the doctor was thrown off his guard, for the woman was 42 years old; she had been married twenty-one years and had never before been pregnant. She was in good general health, and was having excessive flooding.

DR. MARCY: I have seen two other cases. Mrs. M., æt. about 30 years, had been married five years and was never before pregnant. She was a delicate girl, had menstruated with difficulty but somewhat regularly. Five months previous to death she suffered from nausea and vomiting with general abdominal discomfort, bearing-down sensations, etc. She had flowed more or less continuously for five weeks. The uterus was somewhat enlarged, anteflexed, easily movable, not tender, os patulous, and the sound was introduced $2\frac{3}{4}$ inches. There was a slight fulness to the right of the uterus, which was slightly tender on pressure; this was supposed at the time to be a periuterine inflammation, and attributed by the patient to overstrain. She was sent to the country for recuperative rest. When seen six weeks later, the patient was sick in bed with symptoms of intestinal obstruction. There was a distinct tumor, size of double fist, a little to the right of the median line, above the pubis, tender and only slightly movable. The uterus was deflected to the left and was $3\frac{1}{2}$ inches in depth. I advised an exploratory laparotomy with the diagnosis uncertain. After consultation with an expert from New York City the operation was declined. Death occurred a few days later, and the autopsy exhibited a ruptured sac with the fetus, 5 inches in length, lying free in the abdominal cavity. The coils of small intestine were agglutinated about the mass, forming a distinctive intestinal obstruction. The pressure from above had been sufficient to cause rupture of the sac, and its contents emptied into the abdominal cavity. Peritonitis supervened, ending in death. Dr. Marcy exhibited the specimen, together with longitudinal sections through the entire uterus, which were exquisitely mounted between glass plates made by Dr. Nelson, of Boston. They are sufficiently thin to serve for projection upon the screen by the stereopticon. The endometrium showed the decidua vera beautifully formed, with its enlarged utricular glands. The uterus was nearly double its normal size.

The second case I saw perhaps twelve years ago in consultation with Dr. Wellington, of Cambridge. A young colored woman was in collapse. She had not menstruated for about three months, and the symptoms of internal hæmorrhage were so clearly marked as to make the diagnosis of extra-uterine fœtation with rupture very probable. I thought laparotomy advised, returned for instru-

ments but, unfortunately, examined the authorities without finding a precedent for the operation; consequently I failed to do what my judgment dictated. Death occurred within twelve hours. The autopsy revealed a ruptured tube, with the lower abdomen filled with clotted blood. The sac was not larger than a hen's egg. I believe the operation would have been feasible.

DR. WM. G. WHEELER: A trouble in making the diagnosis in these cases is that flooding is frequently taken for menstruation. I know of one case in which the fetus was three to four months old and the woman insisted that she had never been pregnant and that menstruation had continued up to a very few days. The sound introduced showed the size of the uterus to be increased, and this was all that could be made out. The woman died and a quart of pure blood was found in the abdominal cavity, together with the fetus. Here hæmorrhage was mistaken for menstruation.

DR. AUGUSTUS P. CLARK: At one time Dr. Thomas advocated electricity for these cases, but lately this method of treatment has been criticized. Can laparotomy be substituted and is it advisable?

DR. HELEN L. BETTS: What else would Dr. Wheeler do?

DR. WHEELER answered: A radical operation.

DR. MARCY: Dr. Thomas has reported seven or eight cases in which the diagnosis was clear, and electricity destroyed the fetus, but the general feeling now is in favor of laparotomy. Dr. Gordon has told of an operation with cure. He opened, removed, and treated as if he had removed a tumor. There has been only one other case in the United States similar to this. If the condition of things is known do not wait for bad results. Probably the cases are more common than are supposed, for the doctors will not report their fatal cases. I know of a case where a woman died at the age of 80, and a calcareous fetus was found which she had carried for 40 years. Also another case where there was a cyst containing fetus bones. Here nature had acted as a surgeon.

DR. WARNER: I recall the case in which the fetus bones were found after 40 years. Dr. Hitchcock made the diagnosis in Dr. Gordon's case and did the operation. If the diagnosis is certain in a given case we may probably save the patient.

DR. CLARK: Thomas does not say anything about the future of his cases. What is the use of destroying the fetus? Septicæmia may supervene if rupture should occur later.

DR. SAMUEL N. NELSON made a demonstration of the

BEST METHOD OF STAINING TUBERCLE-BACILLI IN SPUTUM.

The reader said that his apology for bringing a subject not strictly gynecological before the

society was its manifest importance indirectly. The great advantage to be derived from the examination of sputum was to ascertain the presence or to determine upon the absence of the *bacilli-tuberculosis* before the physical signs of a cavity are apparent or distinct. In a well marked case where percussion elicits relative dullness and sometimes even flatness; when the respiratory sound, obtained by auscultation, is either bronchial or cavernous; and when the correlative vocal signs are present, viz.: either bronchophony with the loud and whispered voice or exaggerated vocal resonance; and especially where these are taken in connection with the cough and expectoration, the emaciation and other symptoms belonging to the history of the disease, then it is not necessary to go to an expert bacteriologist for a diagnosis; for he can only corroborate that which you have already made. When, however, the physical signs are not well marked, a careful examination of the sputum may make certain a doubt, and will guide you materially in the treatment of any given case and aid your prognosis.

A careful résumé of the various methods, with their modifications, that have severally been recommended by various authors for the detection of the bacilli-tuberculosis was then given. In general, they all have the same foundation, viz.: the fixation of a thin layer of the suspected sputum on a coverglass; the diffuse staining of this layer with one of the aniline dyes; the bleaching, which affects everything except the tubercle bacilli themselves, so that they are alone brilliantly stained and all else is colorless; and lastly, not important, but advantageous, the staining with a contrast color, which stains all other microorganisms, both bacilli and cocci, as well as the epithelial cells and pus cells.

The primary staining may be done quickly or slowly. When done quickly, the staining fluid must be boiled in contact with the coverglass-film; when done slowly the staining fluid is applied to the coverglass-film for 12 to 24 hours at the ordinary temperature.

After trying nearly all of the methods that have been recommended for the primary staining, the reader said that he preferred the rapid staining, using the formula of Ziehl:

R. Fuchsin	1 part
Alcohol	10 parts
Carbolic Acid	5 "
Water	100 "

Instead of boiling this staining fluid in a watch glass with the coverglasses floating film downwards on the surface of the staining fluid, as is ordinarily recommended, the reader prefers to hold the coverglass film upwards with a pair of forceps, to place a drop or two of the staining fluid thereon, and to boil it by holding the coverglass over the flame of an alcohol lamp. After boiling it is allowed to cool.

For bleaching the reader uses nitric acid, diluted (nitric acid 1 part to water 4 or 5 parts), into which the stained coverglass is dipped (without washing) and at once transferred (without washing) as quickly as possible to absolute alcohol, through which a few passes are made, and then it is washed under the stream of the water bottle. The action of the acid changes the red color of the fuchsin to a nearly black color, but in the alcohol the red color is restored and then fades. Care should be taken not to bleach too much, for by the prolonged action of the acid and alcohol, even the tubercle bacilli themselves will yield their color.

When properly bleached the contrast stain, methyl-blue, is applied, in watery solution, and, after washing, the coverglass can be mounted and examined with the microscope, when *the tubercle bacilli, if present, are seen as red rods lying among other blue-stained elements.* A good $\frac{1}{4}$ or $\frac{1}{5}$ inch dry lens will distinguish them, but their characteristic formation can only be seen with higher powers, *e. g.*, the oil immersion, $\frac{1}{8}$, $\frac{1}{12}$, or $\frac{1}{16}$ inch lenses, with an Abbé condenser, *i. e.*, under the best conditions of illumination.

Instead of fuchsin, gentian violet may be used for the primary stain, and, in this case, vesuvin (Bismark brown) must be used as a contrast stain, instead of methyl blue.

Résumé:

A. Stain with fuchsin.

B. Bleach by dipping into diluted nitric acid (1 to 5).

C. Finish bleaching in alcohol.

D. Wash.

E. Stain with methyl blue (contrast stain).

F. Wash.

Then mount and examine with microscope.

After explaining the method of staining the *bacilli-tuberculosis* the reader demonstrated the method by examining specimens of sputum brought for the purpose by members of the Society. The result of the examination was, in each case, satisfactory to the one who brought the specimen, although certain test specimens were brought that were not supposed to contain any tubercle bacilli.

Philadelphia County Medical Society.

Stated Meeting, November 28, 1888.

THE PRESIDENT, J. SOLIS-COHEN, M.D.,
IN THE CHAIR.

DR. WILLIAM HUNT read a paper on

DIABETIC GANGRENE.

There are about twenty pages of the great *Index-Catalogue of the Library of the Surgeon-General's Office* given to each of the subjects of

gangrene and diabetes. There are but two monographs catalogued, one by Giron, Paris, 1881, and one by Peyrot, a student, 1878, who reports, I think, thirty-nine cases; these are not in the College of Physician's Library. Then ten isolated cases are reported in the French journals from 1856 to 1868; most of these are in *L'Union Médicale*. I will give a brief summary of these cases:

1. A case of phlegmon and gangrene of the anterior and external region of the right knee. Free incisions were made. The patient was discovered to have intermittent diabetes. There was recovery from the local lesion.

2. A patient known to be diabetic had his right toe to slough; it was detached with scissors. From this he recovered slowly. He was placed on strict antidiabetic treatment, but was careless and the whole foot became gangrenous. There was great abdominal pain, and necrosis of the gastric mucous membrane was diagnosed; death speedily followed; no autopsy.

3. A diabetic of 60 years of age is reported, who died from extensive gangrene of the thigh and back.

4. A doctor, æt. 65, fell down from an attack of cerebral congestion; never sick before. Diabetes was discovered. This was on the 21st of the month; on the 25th great mortification took place involving the cellular tissue deeply, followed by death.

5. A man had a leg amputated for what was thought to be senile gangrene. He recovered slowly from this, then the other leg was attacked, first at the toes. He was found to be a diabetic.

6. Another diabetic is mentioned with spontaneous sphacelus of the right toe.

7. A colonel with his right foot gangrenous died of diabetes. Other cases are here and there mentioned with spots of gangrene.

8. A man of 70, after great pain, had gangrene, first in left toes, then in right. The disease was thought to be senile, but he was found to be a diabetic. The absence of ammoniacal changes is noted in this case, and the question is raised whether the urine of diabetics undergoes these changes.

9. A case of complete destruction of the plantar aponeurosis by gangrene in a diabetic is reported with recovery from that lesion.

10. A man of 55, cut his corn—gangrene followed and diabetes was present; he died. He had before this no symptoms of diabetes—in fact, was never sick. He went through troublesome family affairs, which he felt deeply, some time before.

These patients where the sex is given were males. Mental troubles are more than once given as a cause. Intermittence in the appearance of sugar is noted in two cases. In fact, in one of them, the interne tells his chief, that he (the

chief) had made a mistake. The interne had examined the urine when sugar was absent, but it returned in full. The majority of these cases were in the better walks of life. But the work worthy of a higher dignity of title than a monograph is by Marchal (de Calvi), Paris, 1864: *Recherches sur les Accidents Diabétiques et Essai d'une Théorie Générale du Diabète*. Some of his cases are among those quoted above. Marchal's book has reports of 133 cases of all sorts of what I may call extra lesions occurring during the progress of diabetes, collected both before and after the discovery. Of the 133 cases, gangrene *per se* occurred in fifty-seven. The seats of it were, in the lower extremities 35, lungs 7, hand 3, pleura 2, shoulder 1. Nucha (not ordinary carbuncle) 2, nose 1 (necrosis). Plantar aponeurosis 2, ribs necrosis 1, forearm 1, back 1, gangrenous plaques 1, although the latter are reported in several other cases. I shall not pretend to particularize these cases I refer any one interested to. My purpose is to show that gangrene in diabetes is something more than a coincidence. The extraordinary case No. 39, almost of itself sustains the position. A man of 58 years, came under observation. The case is given in detail and is thus summed up by Marchal. "Thus in the space of six years from 1850 to 1856, the patient was attacked successively with first, a necrosis of the first phalanx of the second toe, which was amputated; second, with a sphacelus of the whole foot and inferior part of the leg of the same limb, which was also amputated; third, with a skin gangrene of the other leg which gave place to a callous ulcer; fourth, with a gangrenous inflammation of the base of the great toe, which left a deep and intractable ulcer; fifth, with a sphacelus of the first four toes, which were also amputated."

Any fair-minded man would say that, if we can develop so much in such a limited range of inquiry and in such a short time, and then ask himself what might be found out by further inquiry, not only among ourselves but throughout the country, diabetic gangrene is certainly something more than a mere coincidence of the disease diabetes. I sent out a small number of inquiries to physicians and surgeons in our city, selecting those whom I thought would know most about the matter, and also made personal inquiries of some. The questions were: 1. How many cases of diabetic gangrene have come under your notice or treatment? 2. What was the social standing of the patients—wealthy, medium, poor, hospital, or private—their ages and sex? The next question would appear to be rather a side issue, but it was made, in passing, to ascertain whether what is almost universally stated about diabetes is legendary, or is the result of carefully collated observation; it also bears upon gangrene of the pulmonary organs—it is: 3. How many of *all* of your

diabetics had consumption, or died with it, and was there anything like gangrene of the lungs. I received thirty answers, including myself; of these, seven had seen no gangrene. They were Tyson, Longstreth, A. V. Meigs, Hutchinson, Packard, Sinkler, Keen. Twenty-five reported 64 cases, viz.: T. G. Morton 13, Da Costa 5, Hunt 5, Agnew 6, J. C. Wilson 3, S. Solis-Cohen 3 (two of them in consultation with other practitioners), Dr. Brush 4 (one case intermittent), D. F. Woods, J. H. Brinton, S. W. Gross, E. L. Duer, Murray Cheston, W. A. Edwards, J. W. Hearn, 2 each. John Ashhurst, Jr., Elwood Wilson, L. K. Baldwin, W. Osler, James Darrach, A. Fricke, W. F. Atlee, C. B. Penrose, J. H. Musser, W. B. Hopkins, T. K. Morton, 1 case each.

I was particular that the cases should be known by actual examination and record to be diabetic. Thus, Dr. Morton at first answered me that he had seen 20 or 25 cases, not knowing my object. I have no doubt that he has seen that number, for he and I have had our attention drawn to this matter for years, but he actually verified the 13 in his list. Dr. T. R. Neilson was certain he had two cases to report from the Episcopal Hospital, but he found no record of sugar, so I rejected them. I mention these facts to illustrate the care that has been taken. The ages, where given, were: 1 between 30 and 40; 2 between 40 and 50; 11, 50 and 60; 12, 60 and 70; 10, 70 and 80; 2, 80 and 90. One exceptional case of Morton's a diabetic aged 19, in whom gangrenous sloughing took place after a needle operation for cataract, is down, and one of S. Solis-Cohen's cases was a young female. Of the sexes given, 24 were females and 25 males. Of social standing, where given, 16 were wealthy, 23 medium, 9 poor, and of these 6 were in hospital. Dr. Brush reports a most interesting case of a female diabetic aged 40, a lunatic. She had large ecchymoses on her limbs which became gangrenous; she died. The autopsy revealed a gumma the size of a large pea in the floor of the fourth ventricle. The seats of gangrene, where reported, are: Lower extremities—below the knee, 37; thigh and buttock 2; nucha (not ordinary carbuncle) 2; external genitals in female 1; lungs 3; fingers 3; back 1; eyes 1. Had I allowed myself to include ordinary carbuncles and boils in the gangrenes, to which class they belong, the list would have been greatly increased.

How many diabetics have consumption or die of it? Marchal says he has known of but few diabetics to die of consumption, but he is rather inclined to adopt the general view. A pamphlet published at Oxford in 1745, called "A Mechanical Inquiry into the Nature, Causes, Seat, and Cure of Diabetes, with an Explication of the most Remarkable Symptoms," says, if the patient be "too far advanced by a neglect of proper remedies, the person so affected in reality dies of a consumption." Dr. Tyson has notes of 55 cases

in private practice since 1884. Of these, 18 have died, 4 of consumption. Dr. Longstreth says a very large proportion die of pulmonary complications called consumption.

Dr. A. V. Meigs has notes of 5 deaths from diabetes, none from consumption, nor does he know of any consumption in those diabetics who have passed into other hands, nor, as I understand, of any in his father's practice. Dr. James H. Hutchinson remembers 1 diabetic who died of consumption. Dr. Packard remembers none. Dr. J. Ashhurst, Jr., does not remember a consumptive. Dr. Sinkler: none of his cases died of consumption. Dr. Da Costa does not remember a case of gangrene of the lungs, but has seen a sufficient number die of phthisis as to believe in the generally held opinion. Dr. Agnew has seen no consumption, one of gangrene of the lungs. Dr. Elwood Wilson does not remember a death from consumption. Dr. J. C. Wilson cannot answer as to consumption, thinks it not so common as supposed; seen one case of gangrene of lungs. Dr. D. F. Woods has had no consumption deaths. Dr. L. K. Baldwin, one case complicated with consumption. Dr. Osler, two died of consumption, one of gangrene of lungs. Dr. Darrach, no consumption. Dr. S. W. Gross, none; Dr. Keen, none; Dr. A. Fricke, none; Dr. J. H. Brinton none; Dr. Hearn, none; Dr. Hunt remembers one woman who was said to have consumption with diabetes. Dr. Brush, one phthisis death, and reports one lady of 71, three of whose family had consumption; she escaped it. Dr. F. G. Morton, one; Dr. W. A. Edwards, none; Dr. Murray Cheston, six cases, no consumption; Dr. W. F. Atlee, none; Dr. T. S. K. Morton, none; Dr. Musser says he knows the cause of death in nine cases. None of phthisis.

Thus among all the diabetics noted by the practitioners mentioned, and we do not know how many are included, but certainly the 55 of Tyson, the 64 of my collection, the 9 of Musser, and 16 non-gangrenous ones specified by 7 others, in all 144, we find but 11 deaths from phthisis. And yet Dr. Thomas S. K. Morton in an essay on diabetes has somewhere picked up a statement, from an authority whose name he has missed, that 43 per cent. of diabetics are killed by phthisis sooner or later. Roberts, 1885, says that one-half of them die with cough, catarrh, phthisis, and other lung complications, when prolonged to the third year, and Aiken quoting him, evidently in mistake, says to first year. Dr. George B. Wood says, "In the great majority of cases the patients die of phthisis." Drs. Da Costa and Longstreth, whose opinions are entitled to great weight, make general statements in their answers; Dr. Longstreth cautiously stating it is called consumption. From a conversation with Dr. W. Pepper, who gives no return, he adopts the consumption view, and Dr. J. Cheston Morris coincides.

S. Solis-Cohen says: "I cannot find accurate statistics as to consumption. Think at least one-third of the cases that I have seen, died of pulmonary affections." Griesinger, quoted by Niemeyer, says "one-half of the cases die of phthisis." Watson says, "some think phthisis universal in diabetes, but it is not so." Flint, quoting Ogle, reports fourteen cases, with deaths from scrofulous or tubercular disease in seven of them. Niemeyer says "that pulmonary tuberculosis hastens the fatal issue." What one of latest authority, C. Hilton Fagge (1886) says, is important. "Diabetes is frequent cause of a phthisis (almost the 1745 expression) which is peculiarly pneumonic in character. Its relation to ordinary pulmonic disease is still doubtful," and after giving certain facts he says, "hence it supports very strongly the opinion that the pulmonary affection in the disease is not of a tubercular origin." He kept notes of the diabetic deaths in Guy's Hospital and in twenty years out of 40 such deaths, 17 died of phthisis. You will notice how indefinite and general some of the statements above given are, without figures to sustain them. Blau, in his review in the late number of *Schmidt's Jahrbuch*, already quoted as to gangrene under the head of "diseases of the lungs in diabetes," says, in substance, "that the question whether so-called diabetic phthisis is the same as ordinary tubercular disease of the lungs is only to be settled by the proved presence in both of the same bacillus." Authorities, Imérman, Rüttimeyer, von Merkel, and von Leyden, are quoted as having observed absolute differences between the two diseases both from examinations of sputa and also by post-mortem. A case is given in which during life the patient had all the symptoms of tubercular phthisis. Except that bacilli were not found in the sputum, and at the autopsy the appearances were totally different from those found in that disease, and these appearances are noted in the text. The bacillus tuberculosis was nowhere found. A case having almost the same post-mortem appearances as this one is reported by Da Costa, in the *Philadelphia Medical and Surgical Reporter*, vol. i, page 8, January, 1887. The bacillus, as in the preceding case, was absent.

This record, considering the large number of consumptives in communities like ours would seem to show that the cases in point are *consumptives with supervening diabetes, and not diabetics with supervening consumption*. I leave the question for wiser heads to determine. Diabetics die, as my inquiries and experience confirm, with coma, cedema of the lungs, and exhaustion.

I have nine cases to speak of, five of whom were gangrenous, and three rapidly advancing toward it when death overtook them. One was peculiar and unverified; all are dead; one was in medium circumstances, all the others decidedly

wealthy. The ages ranged from 50 to 93, four of them being above 70, five were women, four men. In none of them was the classical emaciation present at any time. The disease was intermittent in two. The urine in one of these cases would range as low as 1010 specific gravity, with slight traces of sugar, and then advance to 1030-1035 with evidence of abundance of it. I took a specimen of this low gravity urine to Dr. Casper Wister, of the Mutual Life Insurance Company of New York. He tested it himself and was much surprised, and concluded not to accept statements of "no sugar," founded upon specific gravity alone. Another case also ranged from low to high at varying times, but not so marked as the first. This teaches us not to be too sure in saying, as we all often do, "there's no use looking for sugar in that," when the gravity is 1020 and under. Austin Flint, Jr., reports a diabetic case with the gravity of 1011½. The seats of the gangrene in five of my cases were, foot and leg below knee three, thigh and buttock one, nucha (not ordinary carbuncle) one.

Gangrenes, as a rule, are generally of the soft or humid kind. This, however, depends much upon the part involved. Where the tissues are succulent, the gangrene will be also of that character; where they are composed mostly of skin, tendon, and bone, they will approach the senile gangrenes in appearance. The remark made by Holmes Coote is applicable. He, speaking of the terms used in the descriptions of gangrene in general, as dry, moist, etc., says, "when death of a part takes place rapidly, the vessels still contain blood and the usual fluids, and the mortified parts are moist and soft. When on the other hand, the death is slower, there is usually a deficiency of the supply of blood; the vessels become empty and the part hardens and withers." There is this distinctive difference between the diabetic and the senile gangrenes according to my observation. The former rarely or never present the clear-cut line of demarcation between the dead and the living parts that is characteristic of the latter. This fact, with a want of the decided dryness and shrivelling of the senile variety, should suggest the diabetic form, but in any case the urine should be examined.

I have this interesting observation to make about one patient: A lady, yet 93 years, who did not have gangrene. This past summer she was in more than usual good health. I know positively she had no diabetes until shortly before her death; not only from the want of rational symptoms, but also from recent examining of the urine. I went with her to Newport in June, and left her there. In passing through Newport in the latter part of July, I saw her; she was perfectly well, and her delight was to drive twice a day. I was at Bar Harbor in August, and received a telegram asking me to come at once to

see her at Newport. She was dead before I arrived, and I learned from Dr. Cleveland, of New York, who attended her, that she was sick but eight days, and had developed an *acute* diabetes, which rapidly proved fatal. I had no hesitation in saying, that had she survived the first fierceness of the attack, she would have had to contend with gangrene. The opinion was given, not because of her age, but because of the diabetes.

Sugar in the urine has been developed by falls upon the head, and also in certain forms of apoplexies, but I have just made a, to me, most interesting observation.

In January, 1885, a wealthy gentleman, a long-time patient of mine, of most vigorous constitution, then 76 years of age, had an apoplectic seizure, from which he reacted, and finally settled down into a chronic semi-paralytic. On the 9th of this November, 1888, in the evening, I was suddenly summoned to see him by his son-in-law, a physician. He was comatose, face very much flushed, temperature 103° , pulse 120, and had Cheyne-Stokes respiration. There was no increase of paralysis of the extremities. Basic effusion was diagnosed. Under treatment he improved, and was very much better by morning.

His urine during his sickness had been repeatedly examined, and, with the exception, at times, of slight traces of albumen, there was nothing abnormal. On my morning visit, mindful of the symptoms of the night before, I proposed an immediate examination of the urine. This was done, and decided sugar reactions were produced by fresh Fehling solution.

Here was auto-physiology. Temporary pressure upon, and disturbance of the respiratory centers, and also pressure upon the diabetic regions of Bernard. As the effusion disappeared with the mending of the patient's condition, the sugar has gone with it, and now the tests give no traces of it. It will be interesting in this case if the patient survives, to note both as to sugar and as to gangrene.

I had written thus about this case, when I had occasion to make another note. I saw the patient daily for four or five days, when it looked as though matters were about to resume their old course, and I made the next appointment for two days ahead. But on the 15th I was summoned again. The patient was in deep coma, breathing 60 per minute, pulse 150. *The urine gave sugar reactions more decided than before.* Respiration could be stopped by reflex at once—that is, by any peripheral irritation about the mouth or thorax. This would occur on an attempt to give liquids, then after a few automatic adjustments, the breathing would go on as rapidly as before. Within two hours death took place. There was no filling of the bronchi with mucus. The patient simply stopped breathing. Pressure on the pneumogastric centers was profound. It was a

quick and permanent application of the air-brakes.

In practice we all have our puzzling cases. A distinguished, wealthy lawyer was attacked with an obscure disease. It was rapidly fatal. Dr. James Darrach was the physician, and I was sent for in consultation. It is not necessary to give the details. I cannot remember whether the urine was examined; certainly, I think, not for sugar. Symptoms of sepsis were marked, and among the incidents there was enormous swelling of the abdominal walls, both anteriorly and laterally. I made free and deep incisions into the flanks, and from the cellular tissue mephitic gases and fluids, like those that flow from moist gangrenes, came in abundance. I think, in the light of what has been developed in my researches, that that patient died from an acute attack of diabetic gangrene.

There was no consumption, or even a suggestion of it, in *any* diabetic of whatever kind that I have seen, except the one I vaguely remember, which I have already spoken of as being in the hospital when I was resident. I now submit, from what we have heard, whether among all the gangrenes mentioned in books and indexes, viz., traumatic, hospital, senile, symmetrical, spontaneous, puerperal, visceral, infantile, congenital, cutaneous, mephitic, spreading, exanæmic, arterial, static, dry, wet, moist, humid, white, etc., the much-neglected diabetic gangrene should not be included? We have seen that *diabetic* gangrene makes, with good reason, higher pathological claims to notice than most of the kinds above given. I should not be surprised to find, after thorough investigation, that in *numbers*, in civil practice, diabetic gangrenes would be found to hold the second place, traumatic gangrenes, including those from frost-bite, burns, and scalds, only exceeding them.

A few remarks upon the proximate and remote causes of diabetes which also have a bearing upon the production of gangrene. We have seen that diabetes is no disease of the poor in general. Drs. Tyson, Morton, and Darrach will give you some interesting facts about this.¹ I also have a good instance to add, illustrating the enchantment of distance even in science. Last Sunday I was speaking with Prof. Penrose on this matter of the poor and the rich, when he said, "And yet

¹ In the discussion which followed this paper Dr. Tyson said: "In regard to the infrequency of diabetes among the poor no better proof could be given than in the fact that in the Philadelphia Hospital in which more than a thousand patients are present at one time it will often be impossible for weeks to get a case for lecture." Dr. Morton also stated: "An inquiry recently made of the superintendents of our State hospitals for the insane shows that although more than twenty thousand patients belonging to the indigent class have been under the care of the present medical officers of these hospitals, there has not, it seems, been a single case of diabetic gangrene in the institutions at Harrisburg, Dixmont, Danville, Norristown, or Warren." Dr. James Darrach said: "Dr. Hunt has mentioned that diabetes is a disease of the well-to-do, and referred to the rarity of the disease in hospital patients and among the poor. This would appear to be corroborated by the statement of Dr. Jorda, who states that in an aggregate of 22,735 admissions into, I think four hospitals in Lisbon, there was not one case of diabetes, and of 5,700 deaths in 1862, four only were from this cause."

I don't know, Hunt; you remember the cases that used to be in the hospital when we were residents, and the work done in studying them under Drs. Wood and Pepper?" I remember all that, but did not remember the number of cases. I kept my own counsel, and next day I went for the record. The number of diabetics, as such, that were admitted into the hospital during Dr. Penrose's residency, 1851-53, two years, were just *three*; so, in the lapse of time, much work over a few cases is translated into the same work distributed over many cases.

From 1842 to 1888 inclusive, a period of forty-seven years, *fifty-nine* cases of diabetes were admitted into the hospital, an average of 1.28 cases per year. From 1842 to 1848 there was not a case; from 1858 to 1869 there was not a case, and in the first part of this time the Pennsylvania Hospital was practically the only hospital in our city for the respectable poor to go to for treatment. Thus, from the wealthy and middle classes of this community, I have brought to light more than twice as many cases of diabetes, most of them recent, as have been treated in the Pennsylvania Hospital for fifty years.

Diabetes seems, in its affinities, to be more nearly allied to gout than to phthisis. One of Dr. Cheston's gangrene patients was a man over six feet high, weighing 250 pounds. He was a waiter in a private family, and surrounded with all the accessories of wealth. I could not establish that excess in the use of wine or strong drink had much, if anything, to do with the production of diabetes. A diabetic drunkard is rare; I have never seen one. I think, however, that over-feeding plays a much more important part as a proximate cause. Aside from the boulimia that is often an accompaniment of the disease, it will be found that most diabetics are over-eaters in habit. I know that most of my patients were, to say the least, good feeders, and some of them excessive ones, and one was noted in this way. Well-to-do people, in times of peace and plenty, eat too much. The laboring classes may eat as much in quantity, but they work it off. Excess in food clogs, excess in drink crazes; so the former habit has the advantage in morals, but which kills most is a question.

I shall only glance at the theories of diabetes. Faults of the nervous, vascular, and visceral systems have been, respectively by some, and *all* together by others, considered to be at the bottom of the trouble. I incline to deranged vaso-motor effects (stasis or paralysis of the vessels, with or without atheroma or arterial sclerosis) as most explanatory. What better fact could we wish to sustain this position than the influence of disease on virility, a condition almost absolutely dependent upon normal vaso-motor function? Men with diabetes are mostly impotent; Marchal says, always so. He gives some strange cases of marital infe-

licities, such as unfortunate charges of infidelity by wives against their husbands, when really the poor fellows were helpless diabetics. One of these is described as a veritable athlete, and he was an example of the fact that in this disease great and peculiar strength in one direction may for a time coexist with great and peculiar weakness in another. The knowledge of diabetes is ancient, and, in looking over the old records I thought that I might stumble on one of diabetic gangrene, but in this I was disappointed.²

LETTER FROM PARIS.

(FROM OUR OWN CORRESPONDENT.)

Nature and Origin of Tetanus—Compression and Costal Resection in Empyema—Unglazed Tissue Paper for Dressings—Disinfection of Instruments—Muscular Atrophy of the Limbs.

In my last letter I sent you a short extract of a note by Drs. Berger and Richelot on the contagiousness of tetanus. From a communication to the Academy of Medicine on the nature and origin of tetanus, it will be seen that M. Alphonse Guérin does not believe in the equine origin of the disease. He admits that tetanus is inoculable, but what the agents are that are inoculated has not yet been demonstrated. He says that one may inoculate fragments of flesh taken at the neighborhood of the wound which was the seat of tetanus, pieces of spinal marrow of the bulb, of cerebral matter, are equally inoculable. The blood alone is not. These experiments prove that there is a virus, but no one can say in what it consists. The transmission of tetanus by inoculation is therefore acceptable, but that which is not, is that the agents of this transmission are micro-organisms. That which is certain is that the cases of tetanus in the wounded dressed by the procedure of Lister, are extremely numerous. The agents of contagion would therefore be refractory to carbolic acid and to the other antiseptic agents. M. Guérin is disposed to think that this malady is engendered by a poison analogous to strychnine and to toxine of Brieger, which idea, he says, would be more satisfactory to the mind

² Coincident with the reading of the proof of this paper, I received (December 6, 1888) a copy of the Berliner klinische Wochenschrift, No. 47, November 19, 1888. It contains the first part of an article by Dr. Max Schüller, of Berlin, called "Ein Beitrag zur Kenntniss der phlegmonösen und granösen Process bei Diabetes." The author also intimates that gangrene, etc., is more than a mere coincidence in diabetes. He says: "While many cases of glycosuria, as, for example, those following experimental researches upon and injuries of the central nervous system, have found an essential clearing up, the relation between pus formations, furuncle, carbuncle, gangrenous process, and glycosuria is still quite dark. The view that these cases are essentially only complications of an unrecognized diabetes has still its adherents. I now have nothing new to offer as explanatory, and will consider this part of the subject no further."

than micro-organisms. To show that tetanus is not of equine origin, M. Guérin supports himself on the opinion of different authors, and in particular on that of M. Manoury, a veterinarian of Chartres, who, of 150 cases of tetanus that came under his observation, had never treated two tetanic animals in the same form, and had never seen a single case produced by contagion in man. M. Guérin then asks how the cases of tetanus observed at sea and in countries where the equine race does not exist, may be explained?

At the same meeting of the Academy, Dr. Poilaillon, presented, in the name of Professor Dubreuil of Montpellier, a note, in which the latter vaunted elastic compression, combined with costal resections, in the treatment of empyema. The application of the compression is practiced in the following manner: The chest is surrounded by a Sayre's apparatus, except the level of a rib which had been resected. At this level, a tube is placed which enters the pleura and above the cotton wadding. The chest is then tightly surrounded with an elastic band. The compression is made only at the level of the part uncovered, the apparatus of Sayre preserving the other parts of the chest. Every day, before applying the elastic band, a cupping glass is placed on the opening of the pleura, by which means a small quantity of pus is obtained. The author concludes that, with this mode of treatment, the resection, which involves the ribs only to a very small extent, is certainly less dangerous than in Estlander's operation.

Dr. Bedoin has published in the *Union Médicale* an interesting paper on dressing with absorbent paper which is made of unglazed tissue paper, such as is employed for making cigarettes. These dressings are intended to replace gauze, lint, linen or cotton bandages, as being less bulky and less accessible to different septic germs than these latter are, and is also much less expensive. It may be employed with all the antiseptic precautions prescribed by Lister either in a dry or moist state. This paper is an excellent medium for most antiseptic remedies, and whenever indicated, may be prepared beforehand with morphine, belladonna, cocaine, iodine, etc. According to the author, the application of these dressings has been attended with excellent results in various cases, such as wounds, burns, blisters, affections of the skin and eyes, etc. Comparative experiments have shown that the absorbent property possessed by this paper lint is one-third greater than that of cotton lint. It is absolutely necessary to cover the dressings with an impermeable external covering.

Dr. Redard, in a note read by him before the Société de Chirurgie, insisted on the absolute necessity of disinfecting all surgical instruments and objects employed in dressing wounds. He considers that the methods generally employed

for the purpose are defective, for it is only by prolonged contact with the antiseptic substance that instruments and sponges, etc., can be rendered sterile. Disinfection by heat, says the author, is an excellent method, but all instruments cannot be exposed to flame with impunity, and their immersion is only efficient at a temperature of 110° to 120° and when the contact with the liquid is prolonged during three-quarters of an hour for sounds, trocars, forceps, and during ten minutes for bistouries. Glycerine and oil have certain drawbacks, the former emits a thick strong-smelling smoke when boiling, the latter requires an apparatus for regulating the temperature. Dr. Redard highly recommends solutions of chemically pure chloride of calcium, especially when mixed with glycerine, boiling at from 110° to 120° . The method of disinfection by steam at a pressure at 110° with Dr. Redard's apparatus, prolonged during fifteen or twenty minutes is very simple, practicable and infallible.

At the last meeting of the Academy of Medicine in November, Dr. Desnos, physician to the Hôpital de la Charité, read a note on a case of muscular atrophy of the four limbs of very simple evolution, which came on during pregnancy and consecutively to obstinate vomiting. The case was that of a young woman in her third pregnancy, very much anæmiated by previous hemorrhagic metritis and in whom, all therapeutic means having failed, premature labor had to be induced at the fifth month of her pregnancy. From that time, the atrophy made no further progress, it remained localized in the four members, but with the aid of electricity and hydrotherapy improvement rapidly set in and the patient is now considered completely cured. Dr. Desnos entered at length into the pathogeny of these accidents and directed attention to divers hypotheses the most plausible of which being that of a myelitis affecting the anterior horns of the spinal marrow the cells of which preside over the nutrition of the muscular system. DOMESTIC CORRESPONDENCE.

LETTER FROM NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Headaches and other Nervous Symptoms due to Functional Eye-troubles. The Death of Dr. Sands.

At the last meeting of the County Medical Association Dr. Oppenheimer, the well-known specialist, read a paper of much interest and practical value to general practitioners, his subject being, "Headaches and other Nervous Symptoms caused by Functional Anomalies of the Eye." The effect upon health of errors of refraction, such as myopia and hyperopia, he said, had been so extensively

discussed that the necessity for their correction was now generally recognized; and his object, therefore, was to direct attention to the functional errors only. Eye-strain, although frequently overlooked by the busy family physician, was a not uncommon cause of headache, and by its early recognition many a patient might be spared the fruitless use of a long list of remedies in the attempt to secure relief. A number of the best neurologists and general practitioners, however, had gradually during the last few years come to an appreciation of the fact that a considerable proportion of these cases of headache, neurasthenia, insomnia, etc., depend on some functional disturbances about the eyes; and it had been a matter of surprise to oculists even to discover how many of the merely functional derangements of the nervous system, seemingly unconnected with the functions of the eyes, could be relieved by the careful study and treatment of the muscular apparatus of these organs.

Before alluding more particularly to the various symptoms which he had noticed as existing in connection with muscular asthenopia, and which subsequently disappeared, completely or partially, under treatment directed towards the restoration of the muscular balance, he referred to some points in the anatomy and physiology of the ocular muscles, and called special attention to the fact that in all its actions each muscle was steadied and balanced by more or less action of the opposing muscle, and that all the muscles of the eyeball contributed to the steadiness of its motion and the maintenance of its positions. It was to be remembered, he said, that each eye has to be directed to a nicety in order that the image shall fall upon the most sensitive part of the retina, and that both eyes may see the same object, with the result of binocular vision, as it is called. It was also to be borne in mind that the tractor muscles of the two eyes are supplied by six different nerves, and that the failure or weakening of any one of these will disturb the harmonious working of both eyes. Hence it was a marvel, not that we sometimes have muscular insufficiencies and loss of balance, but that we ever have binocular vision at all.

A muscle was clearly insufficient, he went on to say, which could not hold the eye in its proper place against its antagonist and allowed this antagonist to draw the eye to its own side, thus causing a squint. But technically a muscle was said to be insufficient when it could do its work, but did it under such a strain as to cause unpleasant symptoms and sensations. Having described the method of testing for muscular insufficiency, and its variety and degree when present, with prisms, he remarked that the condition of the muscles naturally varied in the same individual at different times and in differing conditions of health. There was, so far as his experience went, no ob-

servable relation between the severity of the symptoms present and the degree of insufficiency; and some people went comfortably about their business with an amount of insufficiency that would drive those of a more nervous organization to distraction.

In most cases that had come under his observation there was some trouble of refraction complicating the muscular difficulty, and in quite a number of them, as he believed, causing it. The headache, which was perhaps the most constant symptom, was by no means confined to the frontal or temporal regions, as might be expected, but might be general, or possibly referred to the vertex or occiput. The pain might be constant, or come on with the use of the eyes, or perhaps only after the eyes had been used for some hours. In some instances it was of a neuralgic character and very severe. Another quite frequent symptom was inability, or loss of disposition, to use the mind; and, strange to say, patients thus affected are the ones most apt to complain also of insomnia. Dizziness, or some form of vertigo, was also a common symptom, and it was sure to be complained of where the muscles were barely able to maintain an equilibrium; so that the least lapse would bring on diplopia. In one case severe tinnitus aurium, in addition to headache and dizziness, was promptly relieved by the wearing of appropriate glasses. Those who derived great pleasure from reading were apt to be depressed on discovering that they were no longer able to use their eyes *ad libitum*, and this depression was likely to produce in persons of a nervous temperament all sorts of neurasthenic symptoms. A radical change was often observed in this class of patients as soon as they found that they could use their eyes with comfort again.

In regard to the treatment, Dr. Oppenheimer took a very common-sense view which commended itself strongly to those present, and he did not hesitate to express his pronounced disapproval of the teachings of Dr. George Stevens, the well-known champion of tenotomy. He quoted a paragraph from a recent article of Dr. Stevens in the *Archives of Ophthalmology*, the gist of which was as follows: If there is a lateral balance and a vertical balance to your test, but the outer muscles do not appear quite as strong as they should be, according to an arbitrary standard; and if you do not increase the strength of these supposedly weak muscles by practice of a few minutes at a time for several days, and do not succeed in awakening them either by resting them or letting prisms do their work for them—then an operation is undoubtedly permissible. If, said Dr. Oppenheimer, we remembered that this operation would be a tenotomy of the internus muscle, the muscle which of all others needed to be strong in order to converge properly, and that there was more or less convergence required for all distances within 20 feet (which meant, in a city, almost all the

time), we got an idea to what a dangerous extent a hobby could be ridden. In such a case he himself would say: If a weak prism, worn for a few days, gives relief, let the patient continue to wear it, and when it ceases to answer, increase its strength as required. So far from setting up an absolute standard for the strength of each set of muscles, and dividing tendons until this standard was reached, he believed it was as irrational to set up a standard of muscular power, and call deviations from this abnormal, as to set up a standard of weight for an adult man and call every one not coming up to this weight atrophic. He did not wish to have it inferred, however, that he did not tenotomize the internus for a pronounced insufficiency of the externus. He had certainly had some excellent results from doing this when he thought it really indicated; but he said he did not operate for ailments imagined by the patient or the physician, nor did he claim to make effectual cures of epilepsy or chorea by performing tenotomy.

Having given the details of his method of treating these cases of eye-strain for headaches and other nervous symptoms, he summed up the treatment as follows:

1. All hygienic and medical indications to be carefully carried out by the attending physician.
2. A most careful correction of the refraction and accommodation (which in itself is not infrequently sufficient to effect a cure).
3. Correction of muscular insufficiencies, begin with a less degree of strength than apparently necessary, and increased if this should prove insufficient.

4. Tenotomy, if prisms do not relieve, or if they cause too much discomfort of themselves.

And, finally, when the patient can use his eyes with comfort with the correction given him, I rest satisfied, and cannot think any operation justifiable under these conditions.

When it was necessary to use prisms of such high degree as to give the patient the uncomfortable sense of everything being convex or concave, he advised tenotomy, and in performing this he follows the method of Snellen; beginning at the middle of the tendon and gradually cutting outward as far as might be required. In the slighter grades of insufficiency he greatly preferred the use of prisms to tenotomy for the following reasons:

1. It was the easiest for the patient.
2. It was usually sufficient to restore the patient to the comfortable use of his eyes.
3. Restoration to perfect health and condition quite often restored the equilibrium of the muscles, and a tenotomy might under those circumstances incline the balance in the opposite direction. In this connection he said that he could not too strongly express his conviction that out-of-door exercise and all other hygienic and medical means to restore the general health are most important adjuvants to the special treatment.

The sudden death of Professor Henry B. Sands, the eminent surgeon, in the prime of his powers, was a great shock, not only to every medical man, but to the entire community here, where he was so widely known and so highly esteemed. On Sunday morning, November 18, Dr. Sands attended service, as usual, at the Broadway Tabernacle, and, after a hearty meal, started out with Dr. H. H. Smith to see a case of hip disease in Jersey City upon which he had operated three weeks before. He was apparently in the best of health, but on his return, while riding up Fifth Avenue in his carriage, with Dr. Smith, he seemed to be seized with a sudden sense of suffocation, and in less than three minutes had died in the latter's arms. In the meanwhile there had gathered at Dr. Sands home, in 33d street, a company of gentlemen, about forty in number, composed of physicians, members of the Sextet Club, of the Philharmonic Society, and other friends, to enjoy a musical afternoon; and their consternation may well be imagined when the carriage arrived with his dead body. It was at first supposed that the cause of death was apoplexy, but the autopsy, conducted by Drs. Delafield and Peabody, showed it to be the result of heart-failure. The funeral services were held at the Broadway Tabernacle, on the 21st, and were attended by the Faculty and students of the College of Physicians and Surgeons, with which he had so long been identified, large delegations from the Academy of Medicine and Medical Society of the County of New York, and a vast concourse of the general public including many of the most prominent citizens. The Rev. Dr. Wm. M. Taylor, pastor of the Tabernacle, pronounced an eulogy, and in the course of it he stated that Dr. Sands had in mind the erection of an operating theatre at Roosevelt Hospital. "Now that he is gone," said Dr. Taylor, "his brotherhood could erect no more fitting monument to the memory of an eminent surgeon than by giving to Roosevelt Hospital the addition suggested." Unlike the majority, perhaps, of the medical men of New York who have attained the highest rank, Dr. Sands was a native of the city, and this community, therefore, has all the greater reason to be proud of his illustrious achievements and to hold his memory dear.

P. B. P.

The American Academy of Medicine.

Dear Sir:—Many members of the profession will be at one with the opinions expressed in the leader in last week's JOURNAL in regard to the American Academy of Medicine. In reading the report of the proceedings of the Academy in THE JOURNAL of Dec. 8, I was struck by several facts. *First*, the tendency on the part of members of that body to self-adulation. *Second*, the paucity of papers in regard to education. *Third*, the over-exclusiveness of the Academy.

I have watched the Academy for several years. My interest in it was first aroused because of its membership being limited to physicians that have taken the A.B. or M.D. degree in course. This, I admit, prejudiced me somewhat against the Academy, since I am so much of a heretic as to believe that a scientific rather than a classical education is the best preliminary to the study of medicine, notwithstanding Dr. George Jackson Fisher's statement that "The Famous Historic Masters of the Healing Art were men of Classical Education." Men of broad, classical and scientific, education have expressed their conviction that a scientific education *is* a better preparation for the study of medicine than a classical education. That a classical education *was* the best preparation a century ago may be a fact; but the argument is as to the present. Modern science is, we may say, but a little more than half a century old, and the conclusions in regard to what was will not hold for what is. Were Michael Faraday alive to-day, and an American physician, he would be ineligible to the Academy. Were Pasteur an American physician he might knock at the doors of the Academy in vain, for he has no classical education. The classical-education ideas of to-day are burying original investigators that might be, and retarding the progress of scientific medicine. To be an investigator—to be a Naturalist—the physician must be a student of nature, and the classical education is a fetter from which one attempts almost in vain to break loose. It drills the young and growing mind to accept as true what is seen in print, and to regard natural laws as analogues of grammatical rules.

We all admit that medicine is founded on scientific facts—not on classical facts nor on classical knowledge. It is idle to argue that a classical—Latin, Greek and mathematical—education is the best for training the mind. One that holds this antiquated opinion shows an unfamiliarity with the laws of the human mind, so far as known, and should study the matter before claiming consideration for his views. The position of the Academy, then, in excluding physicians with scientific degrees, but without the classical A.B. and A.M. degrees, is a false position, and one that must create a large amount of prejudice against the Academy. For example: the writer has the classical A.M. degree, and is eligible to membership in the Academy. He has never asked for admission, however, because he is aware of two facts: 1. There are better educated men, without any classical degree, and with scientific degrees, who cannot be admitted to the Academy. 2. It is a constant source of regret to him that he was forced through the stereotyped classical course, without adequate scientific training, when he felt, long before he studied medicine, that a good scientific course was the proper training for the study of medicine. He is still of the same opinion,

strengthened by experience and a knowledge of his really defective education; and to become a member of the Academy would place him in the position of believing what he does not believe.

One would think that a Society, the purpose of which is to assist in raising the standard of medical education, could employ its time better than in listening to papers on "The Causes and Prevention of the Opium Habit," "The Treatment of Uterine Diseases by other than Surgical Means," etc. The range of subjects connected with medical education, and preliminary education, is surely broad enough to allow the Academy to have an interesting meeting without troubling itself with questions of therapeutics. So far as the medical schools are concerned, there is pressing need for *practical* study, and Dr. Parvin may be congratulated as having read the only paper, at the recent meeting of the Academy, that has a real and logical connection with the subject of higher medical education. A few words in regard to practical surgery, or practical work in the clinics, would have been much more to the point than "A Few Words Concerning the Academy." The relations between scientific training and logical thinking are more to the point than "The Relations between the General Practitioner and the Consultant or Specialist." That there is a field for the Academy there is no doubt; but it seems that it spends too much time outside its legitimate field.

ARTIUM MAGISTER.

BOOK REVIEWS.

A SYNOPSIS OF THE MEDICAL BOTANY OF THE UNITED STATES. By J. M. G. CARTER, M.A., M.D., Ph.D., Sc.D., Member of the American Medical Association; the Illinois State Medical Society; the Chicago Medical Society; the Chicago Academy of Sciences, etc. St. Louis, Mo.: Geo. H. Field, B.S., M.D., Publisher. 1888.

This is a monograph of 176 pages, in good type and paper. It contains a carefully classified list of the plants and shrubs of the United States reputed to contain medicinal properties of some value; and the supposed properties of each are briefly stated. It contains a list of the abbreviations of authors, a table of orders, an index of both generic and common names, and an index of diseases. In the introduction it is stated that the medicinal plants of the United States embrace about 140 orders; 620 genera, and more than 1,300 species and varieties. The author has expended much time and labor in the preparation of this work, and it will be found very convenient and valuable for reference.

A COMPENDIUM OF DENTISTRY for the Use of Students and Practitioners. By JUL. PARREIDT, Dental Surgeon in the Surgical Polyclinic of the University of Leipzig, etc. Authorized Translation by LOUIS OTTOFY, D.D.S., Lecturer on Physiology, Chicago College of Dental Surgery. With Notes and Additions by G. V. BLACK, M.D., D.D.S., Professor of Pathology, Chicago College of Dental Surgery. 8vo, pp. ix-229. With numerous illustrations. Chicago: W. T. Keener. 1889. Price \$2.50.

From the author's preface it appears that he regrets that the general practitioner so much neglects the specialty of dental science. He believes that the practicing physician should be acquainted with the indications for operations on the teeth, and that he should know enough of dentistry to be able to give advice or express an opinion in matters pertaining to the specialty. This book, then, is written in great part for the physician. The translator, as may be seen by comparing the original work and the translation, has done his work well. The notes by Dr. Black form a valuable addition to the work. The book is profusely and well illustrated.

BRYCE'S VISITING LIST AND POCKET RECORD. Good for any Month or Year. Edited and Published by C. A. Bryce, M.D., Richmond, Va. *The Southern Clinic* Print, 1888. Price, \$1.00, postage paid.

This is decidedly one of the most convenient and valuable of the many *Pocket Visiting Lists* to be found in the market.

MISCELLANEOUS.

THE HEALTH DEPARTMENT OF MINNEAPOLIS.—Health Officer Kilvington has directed a letter to the new members of the council, proposing a plan whereby a very material reduction can be made in the expenses of the health department. The annual expense of the department at present is \$19,760, distributed as follows: Health officer, \$2,000; assistant, a medical inspector, \$900; clerk, \$500; 13 ward health inspectors at \$720 each, \$9,360; quarantine physician, \$1,000; city physician, \$1,500; assistant city physician, \$900; police surgeon, \$900; two meat inspectors, \$2,700.

Dr. Kilvington makes several points as follows: That the present force of health inspectors is made up of men untrained and incompetent to perform the work required of them and that a small, but efficient force, can manage the sanitary affairs of the city. The special quarantine physician is absolutely unnecessary. He proposes that the city be divided into five health districts and a man for each district who shall be chosen by competitive examination. At present there are but two city physicians to visit and care for the sick over a territory of 53 square miles, which is a physically impossible task. He calls particular attention to the food inspection, which should embrace all kinds of provisions, but is now confined to the optical inspection only of meats. He would have a force of five nuisance and two inspectors whose duties

would be to inspect all kinds of food stuffs, and the investigation and abatement of nuisances under the control of the board of health. A professional chemist and microscopist should be engaged for the examination of foods and drinking water. Another important provision is that the city scavengers be placed under the control of the board of health, and that body have power to revoke their licenses for non-compliance with the sanitary regulations of the city. The disposition of garbage can be made self-sustaining under such a system. He estimates that the reorganization of the health office can be effected at the following figures: Health officer, \$2,000; five medical inspectors, \$1,000 each, \$5,000; five food and nuisance inspectors, each \$900, \$4,500; chemist, \$600; microscopist, \$600; office clerk, \$500; a total of \$13,200, and a saving to the city as it is now operated of \$6,560.

DISTRIBUTION OF CONSUMPTION IN NEW HAMPSHIRE.—The extent and distribution of consumption in New Hampshire are admirably set forth in a paper by Dr. Irving A. Watson, the Secretary of the Board of Health of that State. The prevalence and fatality of this disease are illustrated by a number of diagrams. From the figures quoted by the author of the paper, it appears that during the three years 1885-87 there were in the State 2,432 deaths from consumption. It is interesting to compare with this the deaths from other forms of disease. From heart disease there were 1,536 deaths; pneumonia, 1,526; apoplexy and paralysis, 1,421; old age, 1,347; cholera infantum, 918; cancer, 637; typhoid fever, 461; diphtheria, 411. From a careful study of consumption in New Hampshire for the past six years, but more especially from the registration returns of the years 1885, 1886, and 1887, the following conclusions are arrived at:

1. The disease prevails in all parts of the State, but is apparently influenced by topographical conditions, being greater at a low elevation with a maximum soil-moisture, than in the higher elevations with a less moist soil. The prevalence of other diseases also affects the death-rate from consumption.

2. That the season has only a small influence upon the mortality from this disease. The popular idea that the fatality is greatest in winter is shown to be erroneous, the greatest number of deaths occurring in May.

3. That the mortality is considerably greater in the female sex.

4. That no age is exempt from this disease, but that the least liability of its development exists between the ages of two and fifteen, and the greatest number between twenty and thirty. Advanced age does not assure any immunity from the disease, as is generally supposed, but the smaller number of decedents is due to the fewer living persons at that advanced period of life.

5. The death-rate from pulmonary consumption is relatively much the larger among the foreign-born.

6. The average death-rate from consumption for the years 1885, 1886, and 1887, is 12.86 per cent. of the total mortality of the State. In Massachusetts, for the ten years ending 1886, deaths from consumption averaged 16.10 per cent. of the total mortality; and in Rhode Island, for a period of twenty-five years, ending 1884, 16.30 per cent. This shows a greater freedom from the disease in New Hampshire than in the two States mentioned.—*Science*.

DISINFECTING LETTERS.—The *American Analyst* describes as follows the method adopted by the United States Government for the disinfection of letters coming from districts in which yellow fever prevails. Letters from the stricken section are fumigated in a novel way, so that there is little or no chance for the disease being brought northward. The letters are all stopped when they reach the quarantine lines. Each letter is put under a machine with a long arm attached, and this is provided with little teeth punctured at the ends. A powder that is used for fumigating purposes is forced through the arm and down

through the teeth. The arm comes down on each letter, and, while the little teeth are perforating the letter, the powder is blown in between the sheets, disinfecting the letter thoroughly. We had understood that after the perforations were made the letters were exposed to the fumes of burning sulphur. If the *Analyst* is correct in its statement, it would be a satisfaction to know what the powder is which disinfects the letters so thoroughly. So far as we know, there is no powder which has this power when applied in the manner described, and, until we receive further information, we shall look upon the whole process with distrust.—*Science*.

IN THE INTEREST OF THE INSANE.—A conference of the managers and superintendents of the New York State lunatic asylums was held at the asylum in Utica on Dec. 7, in response to a call recently issued by President P. V. Rogers, of the Utica board of managers. The conference was intended to promote an interchange of experiences and the discussion of methods best suited to an enlightened administration of the several asylums, and in the belief that such a conference would contribute to the advancement and elevation of the standard of management in each of these State institutions. Superintendent J. B. Andrews, of Buffalo, read a paper on "State vs. County Care," of which the following is an abstract:

Every State should have a definite and settled policy regarding the care of its insane. As early as 1831, before there were any State asylums, a legislative commission recommended the erection of institutions of sufficient dimensions and numbers to accommodate all the insane. The convention of superintendents of the poor in 1855, passed resolutions that the State should care for all of its insane, and that none of them should be treated in county poor houses. Dr. Gray favored this plan. Dr. Willard, in his report for 1865 to the Legislature, of the investigation of the county houses, gave the number of the insane inmates as 1,300. Public sentiment was so aroused that provision was made for the erection of an additional asylum. Other like institutions followed in due time, but they have not kept pace with the increasing amount of lunacy, and there are to-day in the county asylums outside of the municipal institutions of New York city more than 2,500, almost twice the number reported by Dr. Willard in 1865. These figures show how far short we have come of the standard persistently advocated by the various official bodies of the State. Since their organization in 1867, the State Board of Charities has advocated that the State should assume entire care of the insane, and permissions to do otherwise were only intended to be temporary. The doctor gave clearly and at some length various reasons why the insane are better cared for in State institutions than is possible in county institutions. The chronic insane require a supervision and oversight which cannot be extended to them in association with other paupers. The sentiment for the last fifty years expressed by those in positions of authority has favored the policy of State care. There should be some definite policy adopted and carried out by the State. It is able to do it, and it is a duty which in justice it has no right to shirk.

The following resolutions were adopted:

WHEREAS, Unusual and universal interest has been awakened of late in regard to the care and custody of the dependent insane in the State of New York; and

WHEREAS, Such dependent insane have always been regarded as the wards of the State, and

WHEREAS, It would be prejudicial to the true interests of the insane to depart from this humane conception of their rights;

Resolved, (1) That it is the sense of this joint conference of trustees and superintendents of the State asylums for the insane, that the State should have a definite and settled policy with reference to the dependent insane:

2. That such policy should include as its most important and vital principle the care of all its dependent insane in institutions established and controlled by the State.

THE OFFSPRING OF RABID ANIMALS.—Some observations made by Dr. G. Zagari appear to prove that rabies is not, as a general rule at least, communicated by pregnant animals to their offspring. He experimented with guinea-pigs (six), rabbits (five), and once bitch, and tested the virulence in the thirty-two fetuses removed from the body of these animals while suffering from rabies (which generally causes abortion at an early date). In no case was it found to be capable of producing rabies when inoculated; the amniotic fluid, the placenta, the liver, and finally an emulsion made from the whole body of a fetus were found not to be virulent. In like manner, the milk yielded by the bitch and by two rabbits were found not to be virulent. Dr. Zagari (an abstract of whose paper in the *Giorn. int. d. Scienze Med.* is published in the *Cent. f. Klin. Med.*, 1888, No. 48), considers that the negative results of his researches lends support to the theory that the virus of rabies exists in the nervous system and not in the blood.—*British Medical Journal*, Dec. 8, 1888.

DEATH BY A RARE ACCIDENT.—A little son of Dr. Mueller, of Germantown, was remarkably injured by the rib of an umbrella five weeks ago, and died on December 8. The lad at the time was returning from school, and one of the ribs of an umbrella he carried was loose and dangled. While playfully throwing the umbrella up in the air and catching it by the handle as it fell he missed once, and the loose rib ran up his nostril, causing his nose to bleed freely. On the same evening, after supper, he complained of pains in his head and was put to bed by his father. During the night his breathing was unnatural, and when examined by his father he was found to be unconscious. The physician applied all the proper restoratives without effect and, thoroughly alarmed for his boy's safety, summoned several eminent medical men, among them Dr. Agnew. In view of the history of the case the physicians decided that the rib had extended sufficiently far up the nose to penetrate the brain. After he had lain unconscious for several days an operation was performed, which only resulted in temporary relief.

AN EXPERIMENT IN HYDROPHOBIA.—A very interesting experiment is now being performed in New Jersey on a couple of thoroughbred dogs which were bitten by a mad dog in Philadelphia. The animals were bitten first in the morning at 9 o'clock and then again at 6 o'clock. They were badly lacerated on both the neck and legs. It occurred to a Philadelphia physician that it would be an excellent case for experimenting. The two bitten dogs have been placed in a kennel and yard built especially for them, and guarded in every possible manner against escape. They will be fed exactly the same as the other dogs on the farm; in fact, they will be treated in exactly the same manner as though nothing was expected. From day to day they will be visited by expert dog fanciers and physicians and any change will be particularly noted. Provided the dogs do not show any signs of rabies within a period of three months they will be set at liberty, as incubation is supposed to set in within ten days, but by keeping them under strict surveillance for three months a sufficient time will have elapsed for the determination of the experiment.

DIPHTHERIA ON STATEN ISLAND.—An epidemic of diphtheria which broke out some weeks ago in Tottenville, S. I., threatens to assume serious proportions throughout the island. The first case reported was that of the 5-year old child of Benjamin E. Streeter, proprietor of the West End Hotel, who died after a five days' illness. The disease speedily gained ground in the village. Case after case was reported, both among children and adults, and the efforts of the Board of Health to stay the malady have so far been fruitless. Eighteen new cases were reported at the beginning of the week of December 7, and most of the prominent families in the village have some dead ones to mourn. In one family eight children lie

dangerously sick. From Tottenville the disease has spread to Pleasant Plains, Elkinville, Garretsons, Stapleton, Clifton, Tompkinsville and New Brighton. In these places cases are rapidly increasing. The schools are closed, and the churches will also be closed should the disease not abate.

FATIGUE FROM THE USE OF THE TELEPHONE.—At the meeting of the American Otological Society in Washington, Dr. Clarence J. Blake, of Boston, read a paper on the influence of the use of the telephone on hearing-power. He thinks that this influence must be injurious, because the extremely low intensity, as demonstrated by experiment, of the sounds to be caught from the telephone, compelled a strain of the ear which soon fatigued it, and made it especially liable to injury by the accidental sounds of comparatively high intensity which were constantly liable to be heard. Dr. C. H. Burnett said he had seen several patients who believed that the continued use of the telephone had impaired their hearing. Dr. O. D. Pomeroy gave the case of a patient who said the use of the telephone fatigued her very much, and she thought had made her decidedly worse.

A STATE BOARD OF HEALTH FOR GEORGIA.—DR. SIMS, the member of the Legislature from Lincoln, has in course of preparation a bill creating a State Board of Health. The bill will provide for a board consisting of five physicians in good standing, who will have charge of the quarantine regulations of the State, without, however, clashing with the authority of the local boards.

The measure is the result of a general discussion in the Committee on Sanitation and Hygiene, of the recent epidemic in Jacksonville and of the great variety of quarantine regulations in different parts of the State. One result of the creation of a State Board of Health will be to make uniform the quarantine regulations. The friends of the measure believe that the presence of a State Board will do much to allay the excitement incident upon epidemics.

AN ANIMAL HOSPITAL.—The Trustees of the University of Pennsylvania have determined to build a large hospital and stable for the treatment of diseases of dogs, horses, cows, and other domestic animals. There are more fancy cattle owned around Philadelphia, it is said, than about any other city except Boston, and some of the finest die from want of surgical care. A special department is to be devoted to the care of pet and sporting dogs. A well-known Philadelphia lady proposes endowing a department for cats. The Society for the Prevention of Cruelty to Animals and the Anti-Vivisection both oppose the project.

DR. CHARLES B. WRIGHT, a leading physician of Freeport, Ill., died suddenly of heart disease on December 12. He was born in New York in 1820. Besides being a successful physician he was educated for the law, and for five years filled with honor the office of County Judge.

DR. GEO. F. HUNT, of West Bend, Wis., died on Dec. 10. He was graduated from the College of Physicians and Surgeons of New York City in 1856. He was a State Senator in 1881-82.

WOMEN IN THE PROFESSIONS.—According to the Rev. Elizabeth W. Greenwood, there are 2,432 physicians and surgeons, 105 ministers and 75 lawyers in this country who are women.

DR. HOMER O. HITCHCOCK, of Kalamazoo, died on Dec. 8. He was born in 1827. He was graduated from the College of Physicians and Surgeons of New York in 1855.

GIFT TO THE WORCESTER CITY HOSPITAL.—The Armenians of Worcester, Mass., recently made up a purse of \$200 and presented it to the City Hospital.

DR. HENRY LEFFMANN has been elected Pathological Chemist of the Jefferson Medical College Hospital.

DR. JOHN NORTH, of Keokuk, Kansas, will remove to Toledo in a few months.

Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department U. S. Army, from December 8, 1888, to December 14, 1888.

By direction of the Secretary of War, Col. Jedediah H. Baxter, Chief Medical Purveyor, will proceed to St. Louis, Mo., and Hot Springs, Ark., on public business connected with the Medical Department, on completion thereof to return to his proper station. Par. 13, S. O. 289, A. G. O., Washington, December 12, 1888.

Major Francis L. Town, Surgeon, is relieved from duty at the post of San Antonio, Tex., and will report in person to the commanding officer Presidio of San Francisco, Cal., for duty at that station, relieving Major Henry R. Tilton, Surgeon, and by letter to the commanding General Dept. of Cal. Par. 19, S. O. 286, A. G. O., Washington, D. C., December 8, 1888.

Major Tilton, upon being relieved by Major Town, will proceed to West Point, N. Y., and report in person to the Superintendent of the U. S. Military Academy for duty at that station, relieving Major Charles F. Heizmann, Surgeon. Par. 19, S. O. 286, A. G. O., Washington, December 8, 1888.

Major Heizmann, upon being relieved by Major Tilton, will proceed to San Antonio, Texas, and report in person to the commanding officer of that post for duty, and by letter to the commanding General Dept. of Texas. Par. 19, S. O. 286, A. G. O., Washington, December 8, 1888.

Capt. James A. Finley, Asst. Surgeon, is relieved from duty at Ft. Buford, D. T., to take effect upon the expiration of his present sick leave of absence, and will report in person to the commanding officer at Ft. Assiniboine, M. T., for duty at that post. Par. 19, S. O. 286, A. G. O., Washington, December 8, 1888.

Capt. Alonzo R. Chapin, Asst. Surgeon U. S. Army, is granted leave of absence for fourteen days, to commence on or about December 24, 1888. Par. 1, S. O. 261, Hdqrs. Div. of the Atlantic, Governor's Island, New York City, December 11, 1888.

Capt. Richard D. Johnson, Asst. Surgeon, is relieved from duty at Ft. Adams, R. I., and will report in person to the Superintendent of the U. S. Military Academy, West Point, N. Y., for temporary duty at that station. Par. 19, S. O. 286, A. G. O., Washington, December 8, 1888.

Official List of Changes in the Medical Corps of the U. S. Navy for the Week Ending December 15, 1888.

Surgeon Thomas N. Penrose, ordered for examination preliminary to promotion.

Medical Inspector A. S. Oberly, ordered before the Retiring Board.

P. A. Surgeon S. H. Dickson, detached from the "Richmond" and to the "Pensacola."

P. A. Surgeon Richard Ashbridge, detached from the "St. Louis" and to the "Richmond."

Asst. Surgeon Ernest W. Auzal, promoted to P. A. Surgeon.

Asst. Surgeon F. W. F. Wieber, promoted to P. A. Surgeon.

CORRIGENDA.

In the report of the discussion of the paper entitled "The Medical-Legal Aspects of some Injuries of the Spinal Cord," the last line, p. 850, should read, "Spinal concussion can be as limited as concussion of the brain is." In the 14th line from top 2d col. p. 856, for "should" read "from." In the 7th line, "or" should follow the word "ataxia," and the sentence close with "perverted sensations." In line 22 is printed "commotio cerebri" instead of "commotio spinalis."

ORIGINAL ARTICLES.

THE DETERMINATION AND TREATMENT OF HYPERMETROPIA.

Read before the Chicago Ophthalmological Society, on February 17, 1888.

BY W. FRANKLIN COLEMAN, M.D., M.R.C.S., ENG.

PROFESSOR OF OPHTHALMOLOGY AND OTOTOLOGY, POST-GRADUATE MEDICAL SCHOOL OF CHICAGO.

Though I have nothing novel or startling to announce, still, for the sake of discussion of a vexed question, I introduce this subject. How close and general that classical writer, Donders, considers the relation of asthenopia to hyperopia is evident from the following: "It is a great satisfaction to be able to say that asthenopia need now no longer be an inconvenience to any one. The discovery of the simple fact that asthenopia is dependent on the hypermetropic structure of the eye pointed out the way in which it was to be obviated. Could it be otherwise than that, with the correction of the hypermetropia by means of convex glasses, its resulting asthenopia must also disappear?"

While this grand discovery of hyperopia and its correction by Donders has, perhaps more than aught else, accomplished much for the relief of eye-strain, yet we do not find in the correction of hyperopia such a universal panacea as the above would indicate—for asthenopia may occur with any or no error of refraction, and require quite other treatment than convex glasses. However, hyperopia is so prevalent a source of weak sight that no one will question the importance of its accurate determination as a guide to treatment.

There are three questions I wish particularly to introduce and would like to have especially discussed:

1. Is it necessary to paralyze the accommodation in order to prescribe the most suitable glasses?
2. Can the accommodation be completely paralyzed by homatropine?
3. How much of the hyperopia should be corrected with glasses?

My answer to the first question would be, yes; to the second, I think not; to the third, from .5 to 1 D. less than the total if the glasses are to be worn constantly, and the total if they are to be worn for near vision only.

The first question, judging from my own experience, needs little discussion. He, however skilful, who prescribes glasses for hypermetropia by the aid of the ophthalmoscope and test glasses without paralyzing the accommodation will, in my opinion, make many serious mistakes. My impression is most oculists entertain the same view. On the other hand, such men as Hasket Derby, Strawbridge, etc., are (to my knowledge) in the habit of testing and of prescribing with the accommodation active.

Donders says it is seldom necessary to employ mydriatics for the determination of hypermetropia, but it is justifiable for the more accurate study of the connection between manifest and latent hypermetropia. Juler writes: "From the age of 20 to 30 a mydriatic can often be dispensed with—after the age of 30 mydriatics are seldom necessary."

In answer to our second question it may be said many oculists (among them Drs. Agnew and Webster), have given up the use of homatropine, deeming it insufficient for complete paralysis, and have returned to the use of atropine. On the contrary, members of this Society express themselves as satisfied with the use of homatropine in prescribing glasses. Dr. Gradle told us that, after a series of experiments, he concluded complete paralysis could be produced with homatropine.

To the same conclusion has Dr. C. A. Oliver (Philadelphia) come after extended experiments. He says: "The utmost loss of accommodation occasioned by the single instillation of $\frac{1}{20}$ gr. of homatropine takes place in thirty-two minutes, and if, at the time of the utmost action of $\frac{1}{20}$ gr., the $\frac{1}{20}$ gr. was instilled, complete paralysis was established in fifty-four minutes, and remained stationary more than thirty minutes. This allows of the accurate testing of ametropia."

Juler, in mentioning the above results, does not give the method of Dr. Oliver's experiments, so we are not aware whether, after homatropine, atropine was used as a test of complete paralysis, or upon what grounds Dr. Oliver bases his con-

¹ Since writing the above Dr. Oliver has kindly favored me with a letter stating the conditions of his experimental work with homatropine. Ten young eyes were selected "one of which was emmetropic, and the remaining nine most carefully and recently corrected by atropia, and thus, as it were, in a quiet emmetropic state. This fact renders the exact experimental and the ordinary clinical results far different. No one has been more fully aware . . . that homatropine cannot be made to supplement in any way the use of atropia in the proper correction of errors of refraction than myself."

clusions. I have found in several instances the glasses prescribed under homatropine as commonly used, viz.: grs. viij aq. $\bar{5}j$ instilled three to four times in an hour before testing, unsatisfactory, and have obtained a greater degree of ametropia, and more satisfactory results, with atropine, so that I have come to distrust the finding with homatropine and, when possible, substitute atropine.

Dr. Hotz uses in testing a 4 per cent. solution of homatropine, with which he expresses himself satisfied. One minim of this solution instilled twice in one half hour will, according to Dr. Oliver, produce complete paralysis of accommodation in fifty-four minutes. Yet I have frequently used a 4 per cent. solution of homatropine from twice to four times in an hour, and by the subsequent use of atropine determined accommodation had not been completely abolished, for a greater degree of hyperopia appeared under the latter.

To return to our question: Is it necessary to paralyze the accommodation in order to prescribe the most suitable glasses? Formerly my practice was to test and prescribe with the accommodation active, since this is the condition of near vision. With greater experience the result of such a practice has been frequently observed to be unfavorable, and for some time past I have, as a rule, used atropine. Out of many cases which might be cited, two will be sufficient to illustrate the discrepancy between the results of testing with and without accommodation:

1. C. H. H., æt. 11, has had symptoms of asthenopia for one year. With accommodation active, R. V. + 60 C., $90^\circ = \frac{3}{8}$; L. V. + 60 C., $90^\circ = \frac{3}{8}$. Under atropine, R. V. + 16 = $\frac{3}{8}$; L. V. + 16 = $\frac{3}{8}$. Glasses + 20 gave perfect relief.

2. Mrs. Hart, æt. 26; asthenopic. With active accommodation, R. E. + 42, V. = $\frac{3}{8}$; L. E. + 36, V. = $\frac{3}{8}$. Under atropine, R. E. + 30 + 60 C., 105° V. = $\frac{3}{8}$; L. E. + 20 + 60 C., 90° V. = $\frac{3}{8}$. These latter glasses afforded perfect relief after the former had been tried and failed.

To revert next to our second question: "Can the accommodation be completely paralyzed by homatropine?" Tweedy found (*Lancet*, 1880) a solution of homatropine (grs. iv. aq. $\bar{5}j$) produce total paralysis of accommodation. Schell (*Specialist and Intellig.*, Philadelphia, 1883) says a 3 per cent. solution produces paralysis of accommodation in half an hour.

I will cite the following sixteen cases tested by myself, first with homatropine grs. viij to grs. xx in aq. $\bar{5}j$, and subsequently with atropine, grs. iv aq. $\bar{5}j$, in proof that the former does not produce complete paralysis, and does not furnish reliable indications for prescribing.

Case 1.—Miss G., æt. 16. The right eye, under homatropine grs. viij aq. $\bar{5}j$, accepts — 36 C. 180° (1); under grs. xx aq. $\bar{5}j$ + 36 C. $90^\circ = 72$ (2); under atropine grs. iv aq. $\bar{5}j$ + 36 C. 90° (3). The 4 per cent. solution of homatropine was ap-

plied twice in half an hour. The atropine was applied five times during two days. By comparison we notice the 4 per cent. solution of homatropine released .5 D. more of the accom. than the 1.7 per cent., and the atropine released .5 D. more than the 4 per cent. of homatropine +. That is, $(1) + 72 = (2)$; $(2) + 72 = (3)$.

Case 2.—Mrs. H., æt. 26. Complaints of asthenopia and nictitation for years. Has given up reading during the past year, as any attempt would cause headache. Homatropine grs. viij aq. $\bar{5}j$ four times in one hour. R. E. + 30 = $\frac{3}{8}$; L. E. + 20 = $\frac{3}{8}$. Glasses + 36 afforded relief for a time. Seven months later Mrs. H. reports any use of her eyes causes redness and smarting. After atropine grs. iv aq. $\bar{5}j$ t. d. for three days, R. E. + 30 + 60 C. $105^\circ = \frac{3}{8}$; L. E. + 20 + 60 C. $90^\circ = \frac{3}{8}$. These glasses gave perfect comfort in reading.

Case 3.—J. T., æt. 10 years. Homatropine grs. viij aq. $\bar{5}j$ was applied four times in twenty-four hours, and then four times in one hour, and the refraction tested. The R. E. accepts + 8 C. 105° ; the L. E. + 10 C. 75° . A subsequent testing, under atropine three days, gave for the R. E. + 7 C. 105° , and the L. E. + 7 C. $70^\circ + 60$.

Case 4.—M. T., æt. 26. Homatropine (grs. viij) ten times during three hours. R. E. + .75 D. + 1 D. 60° ; L. E. + 1.25 D. + 1 D. 120° . After atropine (grs. iv) six times in twenty-four hours, R. E. + 1 D. + 1 D. 60° ; L. E. + 1.25 D. + 1 D. 120° .

Case 5.—C. N. Homatropine (grs. viij), ten times in one hour. R. E. + .5 D. V. = $\frac{3}{8}$. Thirty-five minutes after atropine (grs. iv), was once applied, R. E. + 1 D. V. = $\frac{3}{8}$.

Case 6.—E. H., æt. 12. The R. E., under homatropine, shows H. = $\frac{1}{8}$; under atropine $\frac{1}{8}$. The L. E. under the former $\frac{1}{8}$, the latter $\frac{1}{4}$. The homatropine was used (grs. viij) four times in an hour, the atropine three times in twenty-four hours.

Case 7.—Dr. X. tested Dr. Y. after using homatropine (grs. viij) three times in half an hour, and prescribed R. E. + .75 D. 55° ; L. E. + 1 D. These glasses were unsatisfactory. Dr. X. again tested with homatropine and prescribed R. E. + .75 D. + .75 D. 55° ; L. E. + .75 D. + .75 D. 100° . These glasses gave more but imperfect relief. I found, after atropine three times a day during three days, R. E. + .75 D. + 6 D. 75° , V. = $\frac{3}{8}$; L. E. + 1 D. + 1 D. 90° , V. = $\frac{3}{8}$. After using these glasses for months Dr. Y. says he can read for two or three hours without any inconvenience.

In the following cases a 4 per cent. solution of homatropine was used, followed by atropine (grs. iv aq. $\bar{5}j$).

Case 1.—Miss F., æt. 25. Homatropine three times in one hour. R. E. accepts + 72 + 60 C. 90° ; L. E. accepts + 72 + 48 C. 90° . After at-

ropine t. i. d. for three days R. E. accepts + 48 + 60 C. 90°; L. E. accepts + 48 + 36 C. 90°.

Case 2.—Mrs. H., æt. 28. Homatropine four times in two and one half hours. R. or L. V. + 60 = $\frac{2}{3}$. Atropine t. i. d. for two days. R. V. + 48 = $\frac{2}{3}$; L. V. + 30 = $\frac{2}{3}$.

Case 3.—A. B., æt. 12. Homatropine four times in two hours. R. V. + 24 C. 90° = $\frac{2}{3}$; L. V. + 24 C. 90° = $\frac{2}{3}$. Atropine t. i. d. for four days. R. V. + 24 + 36 C. 90° = $\frac{2}{3}$; L. V. + 36 + 30 C. 90° = $\frac{2}{3}$.

Case 4.—R. A., æt. 9. Homatropine three times in one hour and 20 minutes. R. V. + 1.25 D. = $\frac{6}{8}$; L. V. + 1.50 D. = $\frac{6}{8}$. Atropine t. i. d. for three days. R. V. + 1.25 D. = $\frac{6}{8}$; L. V. + 2 D. = $\frac{6}{8}$.

Case 5.—J. B., æt. 13. Homatropine applied four times in an hour, and eyes examined twenty minutes later. R. V. + 16 + 36 C. 120° = $\frac{2}{3}$. L. V. + 30 = $\frac{2}{3}$. Atropine t. i. d. for three days. R. V. + 12 = $\frac{2}{3}$. L. V. + 18 = $\frac{2}{3}$.

Case 6.—Mrs. H., æt. 25. Homatropine three times in one hour. R. V. + 60 C. 90° = $\frac{2}{3}$. L. V. + 72 = $\frac{2}{3}$. Atropine t. i. d. for three days. R. V. + 60 + 60 C. 90° = $\frac{2}{3}$. L. V. + 36 = $\frac{2}{3}$.

Case 7.—M. T., æt. 10 years. Had been examined under a mydriatic seven months previously by an oculist, who prescribed glasses + 15 for constant use. These were fairly satisfactory for five months, but during the past two months the letters would blur and head ache in ten minutes' reading. Under homatropine four times in an hour and a half R. V. + 42 = $\frac{2}{3}$. L. V. + 36 = $\frac{2}{3}$. Under atropine t. i. d. for three days R. or L. V. + 36 = $\frac{2}{3}$. At 20' adduct. = 8°, abd. = 6°; V. d. = equilibrium. With accom. R. or L. V. + 36 = $\frac{2}{3}$ +. These glasses gave perfect comfort and were prescribed for constant use.

Case 8.—A. H., æt. 16. Convergent strabismus and choroiditis disseminata. After homatropine four times in one hour R. V. + 9 = $\frac{2}{3}$; L. V. + 9 = $\frac{2}{3}$. After atropine instilled t. i. d. for three days R. V. + 8 = $\frac{2}{3}$; L. V. + 8 = $\frac{2}{3}$.

Case 9.—S. E. A., æt. 12 years. With homatropine four times in two hours R. or L. V. + 36 = $\frac{2}{3}$. With atropine t. i. d. for three days, R. or L. V. + 24 = $\frac{2}{3}$.

An analysis of the first seven cases in which homatropine grs. viij aq. 5j was used followed by atropine grs. iv aq. 5j, demonstrates, in case 4, .25 D. more hyperopia under the latter. Cases 1, 5, 6, .5 D. more hyperopia. Case 2, an astigmatism of .6 D. in each eye was developed. Case 3 shows an added .6 D. ast. in R. eye and 2 D. ast. + .6 D. hyperopia in L. E. Case 7 shows a change of 20° in the axis of the cyl. in R. E., and an increase of H. 25 D. + ast. .25 D. with axis of cylinder changed 10°.

To summarize the last nine cases. There was developed under atropine an increase of hyperopia, as compared with the findings under homatropine,

as follows: In two eyes .15 D.; in two .25 D.; in four .5 D.; in one .6 D.; in three .75 D.; in one 1 D.; in one 1.5 D. In one eye + 1 D. astigmatism disappeared. In one there was .25 D. more astigmatism; in one .33 D. less; in one .5 D. less. In two eyes the refraction remained the same under atropine.

3. How much of the hyperopia should be corrected? As to this question the answer exhibits a befogging diversity of opinion. Donders says: "In very young persons in whom we may expect much latent hypermetropia, and in those who are somewhat more advanced, for example, at 30 years of age, where the range of accommodation has undergone much diminution, glasses which correct only the manifest hypermetropia are scarcely ever sufficient." Again, "If we know Hm. and Hl. we give glasses which neutralize the manifest; and about one-fourth of the latent hypermetropia, in general they will answer the purpose, either immediately or after a few weeks." In their systematic works Carter, Wells, Schweigger and Williams give practically the above formula of Donders for prescribing glasses. Mitterdorf, Wolf and Nettleship say, give full correction in children, while Roosa advises less than full correction, especially in young people. DeWecker advises a correction of less than Hm. in children with high hypermetropia. Landolt, in his splendid recent work, directs glasses for hyperopia of a strength inversely to the range of accommodation. Noyes' rule is full correction if the total H. = $\frac{1}{12}$ or more, and correction of the manifest H. only if the total = $\frac{1}{16}$ or less. DeWecker and Nettleship correct only Hm. in adults. Wolfe (Glasgow) and Lang (London) give full correction, as a rule, and G. T. Stevens recommends it. Juler writes, "Deduct half a diopter from the Ht. when the glasses are to be worn constantly, and give full correction when they are to be worn for near vision." This, in my judgment, is the best rule, of any quoted, to follow. Instead of adopting any method based upon the age of the patient, or the degree of the hyperopia, it is much more simple to include all cases in one formula, as does Landolt, who considers the static and dynamic (accommodation) refraction as one whole, and says, "The convex glasses ought to correct the whole of the refractive defect and disengage a certain quota of accommodation, which will help the person to keep up his ocular work the desired length of time." This "quota" Landolt considers from $\frac{1}{4}$ to $\frac{1}{3}$. In other words, he thinks $\frac{2}{3}$ to $\frac{3}{4}$ of the total power of accommodation can be comfortably used for continuous work. Then his rule in practice amounts to this: Allow $\frac{2}{3}$ to $\frac{3}{4}$ of the accommodation to be used towards the correction of the static refraction and make up the deficit by adding a convex glass. To take one of his examples: Suppose a hyperope of 7 D. has accommodation of 9 D.: with what glass will he

most conveniently work at 3 D.? In order to see at 3 D. a hyperope of 7 D. requires 10 D. of refraction. For this he requires a glass of 4 D.; the 6 D. ($\frac{2}{3}$ of 9 D.) of accommodation allowed, making up the deficit (in total 10 D.).

In designating the law of Landolt for prescribing glasses as the "most simple," I did not intend to subscribe to it, and in practice do not. Clinical experience will, I think, furnish abundant evidence that $\frac{2}{3}$ to $\frac{3}{4}$ of the accommodation *cannot* be used without asthenopic symptoms resulting. Otherwise very few hyperopes would suffer from asthenopia—as can be easily illustrated from Landolt's own table of "amplitude of accommodation." His table gives 14 D. to 7 D. of accommodation from the age of 10 years to 30. From the above it follows the eye could use 9.33 D. to 4.66 D. ($\frac{2}{3}$ of 14 D. to 7 D.) of accommodation for continued effort (Landolt). Consequently, for reading at 12 in. (3 D.) there would be 6.33 D. to 1.66 D. (9.33 D.—3 D. to 4.66 D.—3 D.) of accommodation, which could be utilized (without asthenopia) to correct hyperopia.

This, I think, does protest too much, for we cannot believe that between the ages of 10 and 30 a hyperopia of 6.33 D. to 1.66 D. may exist, with the rarest exception, without symptoms of asthenopia.

Again, to compare the emmetrope with the hyperope, say at the age of 20 years: Suppose each has 9 D. of accommodation; the emmetrope reads at $\frac{1}{3}$ meter with 3 D. of accommodation ($\frac{1}{3}$ of his total), while a hypermetrope of 3 D. would be compelled to use at the same distance ($\frac{1}{3}$ meter) 6 D. of accommodation (*i. e.*, $\frac{2}{3}$ of his total). My contention is, the 3 D. (total) of hyperopia should be corrected with a glass of 3 D., to make the eye equal to the emmetrope in refraction. I do not forget Donders' objection to the above, that the patient cannot at once (with full correction) relax the total amount of accommodation, and therefore accommodates (with the glass) for too near a point, and accommodative is changed into muscular asthenopia. But we know that Donders himself recommended, and now the majority of oculists prescribe glasses stronger than the manifest hyperopia, and that the eye soon adapts itself to these glasses which are changed from time to time for stronger. The principle remains the same if full correction is given at once, *i. e.*, gradual relaxation of the latent spasm of accommodation. Since there are many persons who cannot, or will not, consult an oculist a second time, much less a third or fourth, in regard to changing their glasses, I think it is best to give full correction and direct them to use the glasses by graduated exercise, and to hold the book 15 inches distant, assuring them the eyes will in time adapt themselves to the glasses, which will then not require to be changed until the age of presbyopia. If without putting the accommodation

at rest, we prescribe glasses, or if we atropinize the eyes and give only partial correction, it may happen (however admirable our intention) we will benefit the patient not more or less than might the happy-go-lucky testing of the average optician (whose exclusive prerogative, the public think, it is to fit glasses); the jeweler who displays (with other precious stones) pebbles which he can especially recommend as most cooling to the eyes, or the general merchant at the cross-roads, who is compelled to furnish all sorts of hardware.

I will report only two cases as examples of the result of total correction:

S. E. A., *æt.* 12. Can read only five to ten minutes without headache and other symptoms of asthenopia. Under atropine (grs. iv ad. $\bar{5}$ j) t.i.d. for three days. R. or L. V. +24 = $\frac{2}{3}$ $\bar{3}$. Sps. +24 prescribed, with which he reads by the hour comfortably.

Daisy B., *æt.* 10. During the past six months only very large type could be read, and even it tired the eyes very much in a very short time. After atropine t.i.d. for three days the R. E. accepted +4 D. +.75 D. 90°; the L. E. +4 D. +3 D. 90°. With these glasses there has been (during a three months' trial) no inconvenience in reading.

The favorable results of treating the majority of asthenopes by the correction of their hyperopia with convex glasses are too familiar to make the citation of their cases of any special interest.

A few cases will be reported in which muscular insufficiency being present, the symptoms did not yield simply to the correction of the refraction.

The subject of muscular anomalies and their treatment is too large to fully consider in this paper. I am convinced we too often neglect to test the ocular muscles in examining asthenopic patients, and thereby fail in many cases to relieve.

Miss McG., *æt.* 37. Seamstress. Complains of pain in the eyes during the past year whenever she read or sewed, and she has suffered a good deal from headache. With accommodation. R. V. = $\frac{2}{3}$ $\bar{0}$ = 5 J. 12" + 36 C. 90° = $\frac{2}{3}$ $\bar{0}$; +24 + 36 C. 90° = 1 J. 10". L. V. = $\frac{2}{3}$ $\bar{0}$ = 3 J. 12" + 42 = $\frac{2}{3}$ $\bar{0}$; +18 = 1 J. 10". At 21' adduct. = 10°; abd. = 6° at 12" add. = 14°; abd. = 10°; V. d. = 4°. Converge. Under homatropine, grs. viij ad. $\bar{5}$ j. R. V. +36 + 36 C. 90° = $\frac{2}{3}$ $\bar{0}$; L. V. +24 = $\frac{2}{3}$ $\bar{0}$. Glasses were prescribed. R. E. +24 + 36 C. 90° \odot prism 2° base in. L. E. +18 \odot prism 2° base in. Ten months later Miss McG. reports she is much relieved, being able to sew all day, with glasses, but cannot read in addition. When in good condition the eyes feel pretty well, but at times they pain and smart.

I regret not having used atropine, instead of homatropine, since Miss McG. will not now take time for examination with atropine, and is imperfectly relieved.

Pain in the eyes and head relieved by sphero-

abducting prisms for near vision, and sphero-abducting prisms for distant vision.

Mrs. E., æt. 32. Is neurotic, and of a neurotic family. Has suffered from asthenopia for 12 years. During the past year she has used her eyes only to write and read letters and read familiar music. Has a dull pain in the eyes and head much of the time. For two years (excepting two weeks) has used homatropine (grs. ij ad. 5j) every evening. Without it the eyes ached constantly. With it, and the avoidance of fatigue, the eyes were pretty comfortable. Six years ago an oculist prescribed—under atropin—a sphero. cyl. glass for each eye. It is doubtful whether they gave relief at first. At the end of a year the eyes were worse. Five years since another skillful oculist examined the eyes—with active accommodation—and gave +60 for each eye. He directed exercise of ocular muscles, by converging for a near point. This gave pain and did not benefit. With the +60 glasses she can read only ten minutes. The strength of the recti had not been tested. With active accommodation I find the R. E. + 72. V. = $\frac{20}{30}$; L. E. V. = $\frac{20}{30}$. Refuses a glass. At 20' add. = 24°; abd. = 2°; V. d. = equilibrium 12" With atropine vertical diplopia with prism shows R. E. + 36. V. = $\frac{20}{30}$; L. E. + 6° divergence. 36 C. 90°. V. = $\frac{20}{30}$ at 20' add. = 24°; abd. = 3°; V. d. = equilibrium with sps. Glasses were prescribed, to be worn for distance. R. E. + 36 \ominus prism 2° base out; L. E. 36 C. 90 = \ominus prism 2° base out; for reading R. E. + 36 \ominus prism 2° base in; L. E. + 36 C. 90° \ominus prism 2° base in. Galvanism had been applied to the eyes, but it caused pain and was given up. It had been tried previously, at home, and always caused pain in the head and eyes. Mrs. E. returned in six weeks and stated she had given up the use of homatropin, had worn the glasses for distance and reading, and when she felt well could read three to four hours a day. She had had no pain in the eyes and little in the head. At 20' add. = 26°; abd. = 5°. V. d. = equilibrium. Advised to use gymnastic prisms five minutes once a day. Three months later Dr. E. wrote: "Mrs. E. saw Dr. Moore before she left New York. He was convinced convergence was so excessive as to give occasional strabismus, although at 20' the Graefe test gave equilibrium. He advised tenotomy—full. The result has been very great improvement, and from her increased ability to use her eyes and her absence of headache, I think and hope it will be a cure.

The above result of tenotomy is very interesting and satisfactory. It demonstrates (as Dr. Noyes has pointed out) that the muscular findings by distant testing, are a much more reliable guide to treatment than the findings for the near point. I cannot say whether the gymnastic prisms were used by which means the real relative strength of the external and int. recti would have

been more evident when Dr. Moore tested. Upon referring to my first testing it is noticed that at 20 feet there is facultative divergence of only 2° with dynamic equilibrium, while with the Graefe dot and line test at 12 in. there is dynamic divergence of 6°. Subsequently (3d testing) at 20 feet prism of abduction equal to 5° while ad. = 26°.

Miss M. S., æt. 15 years, an undeveloped delicate girl, who for years had suffered constantly from headache and pain in the eyes. The family physician had been able to give but little relief, so sent the patient to me to have her eyes examined. Miss S. says any attempt to read produces pain in the eyes and brows, flowing of tears and blurring of the type in a few minutes. R. E. V. = $\frac{20}{30}$ = 1 J. 12" + 48 = $\frac{20}{30}$ L. E. V. = $\frac{20}{30}$ = 1 J. 12" refuses glass. At 6 feet Ad. = 13°; Ab. = 10°; V. d. = Div. 8°. Under atropine R. E. + 36 C. 90° V. = $\frac{20}{30}$; L. E. + 30 C. 90° V. = $\frac{20}{30}$. Upon fixation within 12 in. with either eye the fellow eye diverges. Advised arsenic and fat food. After application of galvanism daily for two weeks, the eyes were less sensitive to pressure but the pain was not relieved.

A second testing under atropine gives R. V. + 48 = $\frac{20}{30}$; L. V. + 48 = $\frac{20}{30}$. With accom. R. or L. eye accepts + 48. Directed to wear constantly for distance + 48 \ominus prism 2° base out (each eye). Read with these glasses and with + 36 on alternate days. Commencing with five minutes three times a day, and increase the time one minute daily. Three weeks later, Miss S. can read twenty-seven minutes comfortably with either pair of glasses. Directed now to try the sphero-prisms with *base in* alternately with + 36 and continue to increase the reading time as before.

After six weeks, Miss S. reports she has reached 54 minutes with comfort, and reads equally well with either pair of specs. The headache is unrelieved. At 20' ad. = 24°; Ab. = 6°; V. D. = *Conc.*

Spheroadducting prisms (+ 48 \ominus 2°) were given for distance and sphero, abducting (+ 48 \ominus 2°) for reading, and prisms 6°, 8°, 10° and 12° to be used once daily for five minutes, with the light (as object) at 20 feet. Miss S. returned in six months. Says she can read as long as she wishes now without any inconvenience, and the headache is very much less. Her eyes now accept as the best reading glasses, R. or L. + 72 + 60 C. 90° \ominus prism 2°, base in. The adducting prisms for distance cause headache and are discontinued.

Mrs. S. reports seven months later that her daughter is from home at school, has no trouble in using her eyes for her studies, and rarely suffers from headache.

The good result in this case I attribute to graduated exercise in reading and to the use of gymnastic prisms. Since spherical glasses, sphero-adducting or sphero-abducting prisms could be

worn equally well it is not likely the prisms afforded much relief in reading.

Spasm of accommodation and asthenopia in a patient with total hyperopia = $\frac{1}{16}$, relieved only after the use of atropine for nine and a-half months.

M. B., æt. 9 years, since commencing to attend school at the age of six, has held her book very near, and now reads habitually at four inches. The reading of two or three sentences produces pain in the eyes, brows and jaws.

With accommodation R. V. = $\frac{2}{30}$ = 1 J. 4 to 12 in. + 48 = $\frac{2}{30}$ L. V. = $\frac{2}{30}$ 1 J. 4 to 7 in. + 60 C. 90° = $\frac{2}{30}$. After atropine t.i.d. for three days, R. E. + 20, V. = $\frac{2}{30}$, L. E. + 24, V. = $\frac{2}{30}$. R. specs + 36 for reading. Two weeks later can read two pages before eyes tire. R. + 24, specs to be worn constantly. Four and a-half months subsequently Maud reports there has been no trouble in reading at 15 inches, and she liked the glasses for distance as she could see farther and had no headache, but for two weeks past the eyes have again troubled her in reading. There is again spasm of accommodation. R. Repeat atropine t.i.d. Two weeks later total H = $\frac{1}{16}$ R. or L., R. atropine once daily. Four and a-half months, later the atropine had been discontinued for weeks and reading could be done comfortably without glasses. Advised to continue the use of glasses to prevent relapse.

I think the moderate continued exercise of the internal recti by the wearing of abducting prisms for distance, is much more effectual than electricity, or than the spasmodic gymnastic use of prisms, in relieving muscular insufficiency. Galvanism I have found lessens very much the pain and tenderness of the eyes which accompany asthenopia, but electricity has appeared to me to accomplish little in strengthening ocular muscles.

Gradually increasing exercise of the eyes seems to be as much indicated in asthenopic hyperopes who are not relieved at once with glasses as in emmetropes with weak sight, for whom Dr. Dyer used it with such signal success.

163 State Street.

HEPATIC INCOMPETENCE IN CHILDREN.

Read in the Section on Diseases of Children, at the Thirty-ninth Annual Meeting of the American Medical Association, May, 1885.

BY M. P. HATFIELD, M.D.,

PROFESSOR OF DISEASES OF CHILDREN IN CHICAGO MEDICAL COLLEGE.

A type of patient, very familiar to the physician interested in pædiatrics, is the well-known, sallow, neurotic anorexic child, the torment of herself, parents and the physician. She—for it is more frequently a she than a he—is as a rule dyspeptic, constipated, generally disordered in secretion and yet without demonstrable lesions.

What ails these children? If there happens to be a feverish exacerbation during the day, malaria is usually charged with their infirmities, but quinine aggravates their troubles instead of removing them. Gastric catarrh and the so-called bilious attacks are met with in a certain proportion of these cases but by no means in all; nor does the treatment of the gastric catarrh alone cure these children. General tonics, especially the feruginous, make matters worse, and the most careful physical examination fails to reveal anything except in a very few cases where moderate tenderness and enlargement of the liver may be detected. Beyond dispute these children are not well, but there is no word that will explain their condition, unless we fall back on that much abused term "biliousness." But bilious they are not, in the sense that there is an excess of bile, or its reabsorption to any considerable degree—although there may be sallowness, furred tongue, and stools inclined to a clay color.

Other of their symptoms may be found in Murchison's description of lithæmia, but this is partial and only embraces those cases in which there is a copious deposit of uric acid or the urates in the urine, due to imperfect formation of urea.

Hepatic incompetence is a better term, for it includes not only imperfect nitrogenous transformation, but all other deficiency in the work of the liver. The name has been adopted in regard to the work of the kidneys, and something of the kind is needed to scientifically group together not a few of the morbid conditions of early childhood very unlike in their clinical manifestations, and yet in the writer's opinion, all due to imperfect work on the part of the liver.

Etiology.—In these days of bacteriological laboratories and microbes many and various, it takes some moral courage to insist that there is such an old fashioned organ as the liver and that it may become functionally deranged without the provocation of any bacillus. Such I believe is frequently the case in children with whom organic diseases of the liver are rare, but functional exceedingly common. These functional disturbances may be conveniently grouped into three divisions: Icteric (bilious), lithic, and toxic, according to the prominence of certain groups of symptoms, corresponding to the interference with the three more important functions of the liver. Very likely there are other and fully as important ones not yet recognized, for the general knowledge of the profession in regard to that much abused organ is hardly better than that of Hippocrates, who steadfastly believed that the liver was the home of the emotions, and that a man became melancholy, or choleric, according as it formed an excess of various kinds of bile. The chemistry of the bile and its action upon digestion have been carefully studied upon the lower animals, but there is yet a woeful lack of knowledge as to the

origin of the various bile salts and pigments, and much dispute as to the part they play in the human economy. The bile pigments, in all probability, are derived from the hæmoglobin of the blood and possess decidedly antiseptic properties—as proven by the intestinal fermentation which occurs when they fail to pass into the alimentary canal. Such intestinal disturbance, clayey stools, disordered peristalsis and greater or less degree of icterus constitute the group of symptoms to which belongs the term *icteric*, or bilious in common parlance, arising from this form of hepatic incompetence.

The second, or lithic, group of symptoms, are those so well described by other writers under the head of lithæmia, that they need no repetition here except to mention that here belong all symptoms referable to the liver's failure to transform albumenoids into (soluble) urea. They are the clinking of the body's furnace with uric acid and urates with the accompanying gastro-intestinal, renal and cystic disturbances.

Lastly and by no means least in importance are the toxic or toxæmic symptoms due to the failure of the liver to destroy the toxic substances normally formed within the body. This function of the liver—although it might have been inferred from previous experience in toxicology—seems to have escaped the attention of all experimenters previous to Schiff and Lauterbach, of Geneva (1877). They clearly demonstrated that the liver possesses anti-toxic actions, and if the blood is prevented from passing through the liver it acquires toxic properties not unlike those possessed by conia and allied vegetable alkaloids. Later investigators, notably Gauthier, have shown that these poisonous alkaloids are produced by the retrograde metamorphosis of the tissues of the body during life. To distinguish them from the cadaveric alkaloids (ptomaines) they have been named leucomaines, and this sort of hepatic incompetence should be known as leucomaine poisoning, or intoxication; for these leucomaines are toxic, producing death when hypodermically injected into the lower animals. The symptoms produced thereby, so closely resemble the ordinary manifestations of malaria that we are constrained to believe that much of what passes under the name of "dumb ague" is not malarial at all in its origin but is dependent upon the accumulation within the system of these products of decomposition. It is, in short, a variety of septic poisoning, arising from hepatic incompetence, and any form of treatment which fails to take these into account will in so far be found unsatisfactory and disappointing.

Differentiation.—The differential diagnosis of these cases is not difficult if we can but succeed in freeing our minds from the wide-spread belief that hepatic incompetence cannot exist without clayey, or light colored stools. As has already

been said, they may, or may not be present, for certain forms of hepatic incompetence may exist with normally colored feces and, *per contra*, the liver may efficiently perform its work even with a clay colored stool, due to other causes than hepatic incompetence. Neither does hepatic incompetence require that the liver should be congested and tender, though beyond disputed chronic congestion of the liver eventually leads to incompetence by fibroid contraction and degeneration of its atrophied cells. Nor, again, is it always true that an apparently enlarged liver will produce incompetence, for as Eustace Smith has shown: "the liver is apt to vary in size from natural causes in young children; some having exceptionally short chests which cause the liver, without enlargement, to be displaced a finger's breadth or so below the ribs." Bearing, however, these sources of error in mind, the diagnosis of hepatic incompetency ought to be neither difficult nor uncertain, whether it be attended with the distressing vomiting and purging of a bilious attack or the chronic headache and feverish exacerbations of slow leucomaine poisoning.

Prognosis depends upon the amount of the hepatic incompetence. If complete, as in acute yellow atrophy, or phosphorus poisoning, the result is inevitably fatal. As it is usually met with, the prognosis is excellent both as regards the life of the patient and restoration to health.

Treatment should be both medicinal and dietetic, largely the latter. Many of these cases originate in errors of diet, and cannot be cured except by a correction of the same. Excess of albuminous and stimulating foods and such, is almost universal with the American child, or leads to engorgement of the hepatic veins and of the liver cells in their immediate vicinity, with subsequent atrophy of same according to Eustace Smith. Such cases cannot be cured except by a careful regulation of diet before hepatic incompetence becomes chronic. Starchy foods, fruits and broths are those which require least assistance from the liver in their digestion, are those which should constitute the bulk of the diet of such children, for whom a diet list should be prepared and rigidly enforced. Where intestinal indigestion appears as a complication, peptonized foods ought to be of value, though as a matter of fact, pepsin and salicylic acid ($2 + 1$) has in the hands of writers been of more real value, than any form of peptonized food yet tested by him. The salicylic acid conjoined with compound spirits of lavender (B. P.), is also valuable in those cases, attended with the deposit of lithates in the urine as a well-marked symptom, both of the drugs having, in some way, a decided effect upon the excretion of uric acid in a more soluble form.

Old-fashioned biliousness and gastric catarrh

are satisfactorily treated with alkalies and laxatives, preference in these cases being given to calomel, for we substitute in these cases castor oil, magnesia, etc., we only aggravate after temporary relief. As a hepatic stimulant, that is one which increases the flow of bile, without regard to its expulsion, calomel is, however, far inferior to the bichloride, podophyllin, or even benzoate of ammonia. According to Rutherford's experiments one of these should be employed when hepatic incompetence is becoming chronic, and for the relief of migraine, in similar cases the writer has found no one remedy equal in value to antipyrin. The same is also very valuable in those cases attended with high febrile excitement, often the highest met with in children, except pneumonia and scarlet fever. What the exact chemical action of the antipyrin is, I am unable to say. Perhaps we may learn from Dr. Parkhurst's paper, but I am convinced that in some way it assists in the excretion of these toxic leucomaines, to whose private study I invite your personal attention, being convinced that such investigation will yield in the near future valuable scientific and practical results.

DR. CHRISTOPHER thanked the reader for bringing the subject before the Section, and elucidating the pathology of a very frequent and obscure class of cases. He spoke at some length upon a condition to which he gives the name hyper-digestion; a formation of ptomaines and alkaloids of putrefaction in the intestinal tract. If the liver is incompetent to deal with the excess of ptomaines, some of these are carried into the circulation, and produce their peculiar effects through the medium of the central nervous system, like all other alkaloids. Since ptomaines can only be formed from nitrogenous foods, it follows, that in the treatment of these cases, such foods should be withheld.

He was accustomed to use calomel as a preliminary cathartic, and soda phosphate afterwards in the mornings as a hepatic stimulant. Salol, salicylic acid and naphthaline, he employs as intestinal antiseptics. His treatment has proved very satisfactory.

DR. GEO. WHEELER JONES thought the term "hepatic incompetence" a good one. It was more troublesome than other forms of indigestion in children. He used oil of wintergreen with sugar or syrup. It would relieve the acid diarrhoea. It is not a chemical compound, and he preferred its use to salicylate of soda. He also said that bichloride of mercury in minute doses was more persistent, and acted more upon the deeper structures than calomel. Another remedial agent was common salt.

CONTROL OF FEMALE COSTUME.—A physician of Missouri announces that he will not take a female patient unless he can order the costume as well as the medicine.

A RECTAL PLUG. FOR SENN'S METHOD OF INSUFFLATION OF HYDROGEN GAS.

BY A. H. MEISENBACH, M.D.,
OF ST. LOUIS, MO.

In repeating Dr. Senn's experiments, of insufflation per rectum of hydrogen gas, I found considerable difficulty at times, to prevent the gas from escaping out of the rectum, using the ordinary syringe tip. I found this to be the case in experimenting on dogs, and also on the human cadaver.

Dr. Senn recommends in his paper on "Insufflation of Hydrogen Gas per Rectum," etc., that "an assistant hold the margin of the rectum around the syringe tip."

In order to obviate the inconveniences of an ordinary syringe tip, and do away with the need of an assistant in controlling the margin of the rectum, I devised the herein described rectal plug.

This plug has given great satisfaction, having used it in applying Senn's test in four cases of gunshot wounds of the abdomen which were brought to the City Hospital, and in a case of obstruction of the bowel due to the rupture of a Fallopian pregnancy, where obstruction was produced by an immense coagulum—later case occurring in private practice of Dr. Hornsby, and in which I applied "Senn's Test," demonstrating the value of this measure in diagnosing intestinal obstruction.

In the above applications of Senn's test the plug completely plugged the rectum and effectually prevented the regurgitation of the gas, and allowed the gas bag and plug to be controlled by one person. The plug is made of hard rubber. The annexed cut shows a half size perspective

and sectional view of plug. A represents cone-like plug, with tip similar to ordinary syringe tip. B is a hollow chamber in plug into which extends Tip E, on which is a thread which screws into plug as shown at C. At D on Tip E is a square shoulder and round collar. The square shoulder is for the purpose of allowing a wrench to be used to tighten the tip into plug. Between collar on plug and collar on tip at D a washer is used, so

as to insure perfect air-tightness. The end of Tip E which projects outside of plug is corrugated, so as to easily and tightly fit into rubber tubing from gas bag.

The object of having plug hollow and the tip E project into chamber as shown, is to prevent clogging of the direct communication with the gas bag, when inserting end of plug into rectum, by fæces or mucus which may be in the rectum. Should clogging of tip of plug occur it will not interfere with gas escaping from Tip E into chamber, and can be readily removed or blown out by pressure from gas bag.

I have found that pouring a little sweet oil into chamber, through opening in plug into chamber, in a measure prevents the liability to clogging, as the oil lubricates the sides of opening and facilitates its being readily blown out by pressure from the gas bag.

MEDICAL PROGRESS.

ERYTHROPHLEIN IN CARDIAC AFFECTIONS.—DR. HERRMANN, in a recent number of the *Wiener Klinische Wochenschrift*, gives an account of experiments which he had performed in the clinic of Professor Drasche in the Vienna General Hospital, on the effect of erythrophlein on the diseased heart. It was used in cases of compensated and non-compensated failures of the heart, as well as in cases of fatty heart with slight disturbances of circulation. The drug was used in a solution of 0.002 grams of erythrophlein in 10.0 grams of laurocerasus water, ten drops of this solution being given every hour. In general, the drug was well tolerated, and only in a case of insufficiency of the aorta depending on acute articular rheumatism did the sensation of disgust and great irritation supervene. Retardation of the pulse after the administration of erythrophlein came on in several cases, and this was particularly true of the case of insufficiency of the aorta after 150 drops of the solution had been given for eight days. The number of the pulse-beats was reduced from 100 to 84 a minute, and in another case of insufficiency and stenosis of the mitral valve, the pulsations decreased from 100 to 68 a minute after the administration of 50 drops of the solution, and during an interval of time from mid-day till 5 p.m. This, however, was not constant, as in the last mentioned case the number of the pulsations reached 108 a minute three hours later, although the administration of the solution was continued. In another case of insufficiency of the mitral valve with severe palpitations, the drug was administered for twelve days, and it was not until some days later that the frequency of the pulsations sank from 120 to 96 in a minute, and at the conclusion of the experiment it decreased

to about 84 beats. As to the effect of the erythrophlein on the renal function no particular influence could be observed in some cases, whereas in another series of cases the effect was quite striking. In a patient affected with incompetence of the mitral valve the daily quantity of urine, during an interval of twelve days, increased from 800 to about 1,500 cubic centimètres. In another case of slight fatty heart, where, before the use of erythrophlein, the number of the pulsations was from 68 to 60 a minute, and the quantity of urine reached 700 cubic centimètres, the latter increased to 2,150 cubic centimètres, while the pulse remained unchanged. The disturbances of respiration had also diminished. Erythrophlein had also a marked effect on the pupil. In a patient with incompetence of the mitral valve, persistent dilatation of the right pupil ensued on the sixth day after administration. In another case with insufficiency of the aortic valves, distinct dilatation of both pupils came on on the fifth day; this disappeared some days later when the administration of the drug was discontinued. Kaposi had also observed dilatation of both pupils in a case of poisoning from the subcutaneous injection of two centigrams of erythrophlein (*Journal*, March 24th, 1888). For the sake of comparison, experiments were made with strophanthus. In cases in which erythrophlein exerted no particular influence on the frequency of the pulsations, the arhythmia, and the congestive symptoms, from 60 to 70 drops of the tincture of strophanthus with equal parts of laurel water were administered in the day. The difference was very striking, and the slight effect of the erythrophlein could not be compared with that of strophanthus. In one case, for instance, the frequency of the pulsations after the use of strophanthus soon fell from 112 to 72 a minute, and remained nearly at this rate. The arhythmia had almost entirely disappeared, and the excretion of urine was augmented to a much higher degree than after the use of erythrophlein. Symptoms of poisoning with erythrophlein were observed on only two occasions. The result of the experiments with erythrophlein may be summarized as follows: The drug had a marked retarding influence on the pulse, but the effect was not lasting. This was also true of its diuretic influence. The drug was well borne, and might be tried in cases in which digitalis, strophanthus, and similar medicaments were either not well tolerated or were contraindicated. Erythrophlein did not appear to have any cumulative effect.—*British Medical Journal*, Sept. 1, 1888.

TREATMENT OF TYPHOID FEVER IN CHILDHOOD.—DR. A. JACOBI says: Can typhoid fever be *aborted*? or in other words, can incubation be interrupted? An affirmative answer to this question has often been given, but it is difficult to prove the correctness of the diagnosis in an

alleged case of typhoid fever lasting a few days only. Still, there can be no objection to believing that the proliferation of the poison floating in the blood may be interrupted by antifermentative treatment, and it is certainly either justifiable or advisable to try the effect of otherwise not injurious antifermentatives, such, perhaps, as creolin or bichloride of mercury. As regards the early administration of a large dose of calomel, its effect is notoriously good, no matter whether it acts as a disinfectant directly on the poison, or whether it simply relieves the intestinal tract of the poison introduced, and in progress of proliferation. A child of 3 years may take a dose of 3 or 4 grains; a child of 8 years one of 7 or 8 grains. While the purgative effect of the calomel can be obtained by simply introducing the powder into the mouth, there to be absorbed, it is better in this case to let it be swallowed. It can be safely given during all of the first week of the disease. When, as frequently, there is constipation during the course of the disease, calomel is no less beneficial, but then it must be given in smaller doses, which may be repeated. Small doses of a quarter of a grain to a half grain repeated several times a day, will even have a good effect after diarrhœa has been present and been relieved.

With regard to the *general treatment* of the typhoid fever of children, we are equally liable to injure either by overactivity or by neglect. The so-called *expectant* treatment has its great dangers in the hands of those who make it their invariable rule; it is safe in the hands of those only who have learned to treat the sick rather than the sickness. The air in the sick-room must be cool, the windows open. Drafts, it is true, must be avoided, but screens around the bed will permit the opening of both windows and doors. The bed-sheets must be smooth; four or eight safety-pins will fasten them to the corners and sides of the mattress. At an early period the whole surface ought to be washed with either water alone or with alcohol and water. The hair, when long, ought to be cut. The children must be allowed plenty of water. Those who are liable to have dry lips and tongue must be made to drink a small quantity of either water or dilute muriatic acid in water, ten minims to the tumblerful, in small quantities or ever ten or twenty minutes. Fissures around the lips or in the tongue ought to be washed with a saturated solution of boracic acid, or when bleeding, should be painted once a day with a mild solution of nitrate of silver (not more than 1 per cent.) and afterwards painted with an ointment consisting of boracic acid and lanolin.—*Archives of Pediatrics*, December, 1888.

CREOLIN AS AN ANTISEPTIC.—EISENBERG has found that a 2 per 1,000 mixture of creolin

killed the cholera bacillus and the streptococcus of pus and of erysipelas within two minutes; the bacillus of anthrax was killed in five minutes, while the typhoid bacillus and the staphylococcus of pus were still alive after one hour. This last organism, as well as tetragenes, was killed in ten to fifteen minutes by a 2 per cent. mixture. Compared with carbolic acid, it was found that a 3 per cent. mixture of creolin killed the spores of the anthrax bacillus in two days, a 6 per cent. mixture within twenty-four hours, while a carbolic acid mixture up to 8 per cent. had no effect on the spores within seven days. A similar comparative result was obtained with the hay bacillus, and the superiority of creolin over carbolic acid was further shown by its greater power in preventing the growth of organism in cultures. Creolin is not poisonous, as it may be given in large doses to dogs without deleterious effect. Eisenberg recommends its use in surgery in place of corrosive sublimate, carbolic acid, and iodoform.—*British Medical Journal*, Nov. 10, 1888.

CONSTIPATION IN INFANCY.—In cases that do not recover under proper dietary management, DR. EUSTACE SMITH recommends:

R. Tinct. nucis vom. ℥ss.
Tinct. belladonnæ ℥x.
Infusi senneæ ℥xxx.
Infusi calumbæ ad ʒj.

This may be given thrice a day at first. After a time, two doses will be enough; and before long, one dose at bedtime. An equally good or better prescription is:

R. Tinct. nucis vom. ℥ss.
Ext. cascariæ sagradæ liq. ℥xx.
Tinct. belladonnæ ℥x.
Inf. calumbæ ad ʒj.

The keynote is the combination of nux vomica with belladonna and some gentle laxative. Dr. Smith also recommends, where the motions are very dry, a saline aperient:

R. Quinîe sulph. gr. ʒ.
Acid. sulph. aromat. ℥j.
Tinct. nucis vom. ss.
Aque ad ʒj.

For a child of 6 months.—*Medical Record*, November 24, 1888.

INFLUENCE OF ANTIPYRETICS, PARTICULARLY OF ANTIPYRIN, ON THE AMOUNT OF GLYCOGEN IN THE LIVER.—MM. LÉPINE AND PORTERET have found that the administration of antipyretics (and they used antipyrin principally) decidedly increases the amount of the hepatic glycogen and diminishes that of the hepatic sugar. The antipyretics are obstacles to the transformation of glycogen into sugar, and the fact seems to be in perfect harmony with the recent work of Chauveau on the consumption of glycogen and the production of heat.

Address

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 68 WABASH AVE.,
CHICAGO, ILLINOIS.

All members of the Association should send their Annual Dues to the Treasurer, Richard J. Duglison, M.D., Lock Box 1274, Philadelphia, Pa.

LONDON OFFICE, 57 AND 59 LUDGATE HILL.

SATURDAY, DECEMBER 29, 1888.

IMPORTANT NOTICE.

Hereinafter all letters, papers, notices and exchanges, designed for THE JOURNAL, should be addressed to "THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 68 Wabash Avenue, Chicago, Illinois." And persons having inquiries to make, or business to transact, will receive prompt attention at the same place until further notice.

CLOSE OF VOLUME XI.

The present number closes the eleventh volume of this journal, and completes the first five and a half years of its publication. As its readers already know, it also terminates the editorial services and management of the present editor.

Though already advanced in life and overburdened with professional work, he accepted the additional heavy responsibility, in 1883, of attempting to establish THE JOURNAL of the Association on a permanent financial basis, and at the same time make it a potent influence for counteracting the disintegrating tendencies of an excessive specialism and an open opposition to the National Code of Medical Ethics; and thereby preserve intact and further develop the grand National organization of the profession of this country that had been so well founded by the National Convention of 1846-7. Only two brief years had passed when the persistent and unnecessary controversy concerning the organization of the Ninth Interna-

tional Medical Congress was developed, and forced upon him an additional amount of labor difficult to bear. But the remarkable epidemic of professional controversies that has characterized the last decade has subsided, and should be left for the future historian.

In the meantime, THE JOURNAL, that had been commenced in July, 1883, when there were only about 1,000 members who had paid their dues annually, as shown by the Treasurer's report at the meeting in Cleveland that year, has been issued every week from that time to the present, when about 4,000 members are paying dues annually, to which may be added a considerable list of paying subscribers who are not members of the Association. The income, that was \$5,008, as shown by the Treasurer's report in 1883, has increased, as shown by the same officer's report in 1888, to \$25,649, and the Association has become owner of its own printing-office and materials, valued at \$2,373.90, without one dollar of indebtedness in any quarter. The pages of reading-matter in THE JOURNAL have been increased until they number eight more than those of any other weekly medical journal in this country; and in quality of paper, type and illustrations they are excelled by those of no other. Equally gratifying is the fact that the Association has not only quadrupled its paying membership during the last half decade, but it has extended the scope and increased the efficiency of its working machinery as represented by its Sections, and its general meetings have been characterized by greater harmony and a more active spirit of scientific investigation; while the several State and local medical societies, upon which the whole fabric of permanent National organization rests, have been correspondingly increasing in their efficiency and influence for good.

Having thus more than realized all the ardent hopes of success that inspired him in commencing his editorial task in 1883, it is with the greatest pleasure that he now surrenders the honorable and responsible position to him who has been selected by the Board of Trustees to fill the same. DR. JOHN B. HAMILTON, for ten years the efficient Supervising Surgeon-General of the U. S. Marine Hospital Service, and late Secretary-General of the Ninth International Medical Congress, needs no introduction to the readers of THE JOURNAL, and no eulogy by me. In the prime and vigor of

his manhood, with high literary and professional attainments, and well trained executive ability, I welcome him to a field of labor that will afford full scope for every noble attribute of which he is possessed. May he live to honor the position many years, and may THE JOURNAL, the American Medical Association, and all the State and Municipal Medical Societies in affiliation with it, continue to hold the whole medical profession of these United States in one grand harmonious organization, ever increasing in numbers, in scientific attainments, in skill for the relief of human suffering, and in reverence for that beneficent Deity who holds the destiny of individuals and nations alike in his own hands, and yet does not allow the poorest of his creatures to suffer without his notice. Finally, the retiring editor cordially wishes that all the readers of THE JOURNAL and its incoming editor may enjoy a truly *Happy New Year* for 1889, and repeat the same with each annual return for all the years to come.

PROFESSIONAL ABORTIONISTS.

The preface to the first edition of Sydenham's "Method of Curing Fevers," which appeared in 1666, opened as follows: "Whoever takes up medicine should seriously consider the following points: firstly, that he must one day render to the Supreme Judge an account of the lives of those sick men who have been intrusted to his care. Secondly, that such skill and science as, by the blessing of God, he has attained, are to be specially directed towards the honor of his Maker and the welfare of his fellow-creatures, since it is a base thing for the great gifts of heaven to become the servants of avarice or ambition. Thirdly, he must remember it [is no mean ignoble animal that he deals with."

Within the past two weeks the public and the medical profession of Chicago have learned, through exposures in the *Chicago Times*, that there are numbers of professional midwives and licensed physicians in this city, who declare that for a money consideration they will commit the loathsome crime of abortion, or, if some will not, they can recommend others that will. The *Times* has printed the names of midwives and physicians who declare they are ready to do murder, and most foul murder, for money, or else recommend some one that will commit a violation most wicked

of the laws of God, Nature, and man. As between the assassin, or the thief, and the man that recommends the assassin or thief there is but little difference. Between the licensed midwife-abortionist and the licensed physician-abortionist, what is the difference? It is one of degree, and the deeper degree of infamy attaches to the latter. He is supposed to be more intelligent, to be actuated by higher and more noble principles, and to have for the chief end and aim of his life-work the preservation of human life.

Nothing we can say in this age can paint the crime of abortion in all its loathsomeness, nor its perpetrators, and the inciters to or abettors of its perpetration in all their moral blackness and professional degradation. "The licensed Herods" that have been exposed, that are willing to commit murder, that have blackened the good name of our noble profession, and given themselves over to the eternal infamy and abhorrence of all mankind, have but themselves and their sordid motives to thank for the present exposure, and its possible consequences.

In expressing themselves as willing to commit this crime, or to recommend others that will, men show themselves possessed of consciences too near in kind to those of brutes and beasts to be reached by moral agencies. What remorse may come to them will be born of the fact of exposure—the sorrow of the thief that he is caught.

It is not our purpose, nor is it proper for us to be judge and jury in regard to these cases. The State of Illinois has laws, and instruments for their execution; it has a State Board of Health; and there is a large medical society in this city, to which some of the offenders belong. Men that will commit abortion are unfit for citizenship in any civilized state, are too far lost to moral responsibility for the profession of medicine, and too degraded to be the associates of honest men. Then let the police, the courts, the State Board of Health, and the medical societies take the record furnished by the *Times* and deliberately proceed with the execution of the laws of the State and the ethics of the profession with strict impartiality and unswerving justice. To leave the matter where it is, a simple newspaper exposure, will result in its horrors being forgotten in six months, while the black list will remain as a convenient directory for those who may be in want of abortionists in the future.

Will honest men endure the fellowship of lawless, abhorrent and infamous men that traffic for personal gain in the weakness and shame of poor erring humanity?

Criminal abortion, the National disgrace, has culminated in the exposure in Chicago. It is to be regretted that the matter was not worked up at the same time in other cities, so as to clear the country of the harpies that foul the medical profession.

After all, we may trace the origin of this matter, in a great measure, to our system of medical education, and to the attitude of the public and the newspapers in regard to higher medical education and State regulation of medical education and practice. We do not claim that all highly educated men are moral, nor that badly educated men are always immoral. But if the public and the newspapers will cease their interference with plans and projects for higher medical education, and for more stringent regulation of the practice of medicine, the medical profession will be improved, both for its own good and for that of the public.

EDITORIAL NOTES.

FOOD ADULTERATION IN MINNESOTA.—The report of Dr. Drew, of Minneapolis, Chemist to the State Dairy Commission, just made public, shows that the adulteration of food in Minnesota has assumed alarming proportions. In his report Dr. Drew says that no evidence of adulteration was discovered in the samples of flour and bread examined. In baker's chemicals nearly all were adulterated. Of 29 samples of cream of tartar examined 17 were adulterated, and bicarbonate of soda was only half pure. In the baking powders commonly used, ingredients were found which were likely to lead to the impairment of health. The alum powders are declared to be cheaply made and contain large proportions of flour or starch. Twenty samples of teas were examined and three found to be adulterated. Only 3 out of 7 samples of ground coffee were found pure. Of 81 samples of spices 64 were adulterated and 17 were pure. Out of 34 samples of "pure cider vinegar" 9 were found pure and 2 adulterated with water. Twenty-three vinegars, not cider, were found to be adulterated with water. Of 10 samples of cider all proved

to be apple cider adulterated with glucose sirup, citric or tartaric acid, or of a wholly fictitious character. All but one contained acids prejudicial to health. Adulterations were found in sugars, confectionery sirups, lard, honey, and in almost every article examined.

EXECUTION BY ELECTRICITY.—A committee of the New York Medico-Legal Society has made a report on the best method to be followed under the law for execution by electricity, which goes into effect in that State on January 1. It will be remembered that some unfavorable criticism was given upon the proposed method by a number of physicians in New York. The reasons given against execution by electricity were two, viz.: that it was not certain enough; and that if successful it was too humane, as it defeated the ends of justice by robbing the criminal's demise of all its terrors. No answer is needed to the latter reason, and the above-mentioned committee's report embodies directions which, if followed out, will make death as certain as it is swift. A stout table, covered with rubber cloth, is provided, upon which the prisoner is firmly bound. One electrode is inserted in the table in such a manner that it will impinge upon the spinal column between the shoulders; the other electrode is pressed to the back of the prisoner's head, the hair being cut close and moistened with warm water. A dynamo generating an electro-motive force of at least 3,000 volts is recommended, the current to pass alternately for thirty seconds. It is anticipated that these specifications will meet the approval of the State authorities.

POISONING FROM FALSE-TEETH PLATES.—A case of supposed poisoning from denture plates is reported from New Haven. The sufferer recently bought a set of false teeth with a rubber plate. He had worn them but a short time when his tongue began to swell. This continued until it was much beyond the natural size. His eyelids also swelled up so that he was blind for a time, and other parts of the body have been similarly affected.

DEATH AFTER A LONG FAST.—A man in Kansas City died on Dec. 16, after a fast that began on Nov. 1, in which he took only a little water occasionally. He was a sufferer from renal disease, and after Nov. 1, could not be induced to take food.

SOCIETY PROCEEDINGS.

Philadelphia County Medical Society.

Stated Meeting, November 28, 1888.

THE PRESIDENT, J. SOLIS-COHEN, M.D.,
IN THE CHAIR.

(Concluded from page 893.)

DR. WILLIAM HUNT read a paper on

DIABETIC GANGRENE.

DR. THOMAS G. MORTON, in opening the discussion, said: Thirteen cases of diabetic gangrene have come under my observation, generally in consultation. In all instances the disease involved some part of the lower extremity, generally originating in one or more of the toes, or about the dorsum of the foot. Many years ago I witnessed a needle operation for cataract in a young girl who was known to be markedly diabetic; sloughing and gangrene of the orbital contents resulted, and death by coma occurred on the third day. With some few exceptions, the patients I have seen with gangrene in the course of diabetes, have been in good circumstances. I refer to this because it has been suggested that this disease more frequently occurs among those who are surrounded by the comforts and luxuries of life, and not among the poor. An inquiry recently made of the superintendents of our State hospitals for the insane shows that although more than twenty thousand patients belonging to the indigent class have been under the care of the present medical officers of these hospitals, there has not, it seems, been a single case of diabetic gangrene in the institutions at Harrisburg, Dixmont, Danville, Norristown, or Warren. Gangrene in diabetes, in the cases I have seen, has generally started in a local inflammation, resulting from some very trivial cause; on several occasions I have known it to follow the operation of cutting a corn. The occurrence of gangrene in diabetes seems to be a certain indication of great nervous exhaustion, and of a general condition most critical. Although I have observed gangrene as a result of diabetic condition in parts of the body other than the extremities, notably diabetic carbuncular disease, yet gangrene appears more often in the toes and feet, where there is but a moderate amount of cellular tissue, and where the circulation in such cases is apt to be feeble.

The surgical treatment of this form of gangrene can generally be but palliative, most of the

cases I have seen have been promptly fatal. The ordinary principles of surgical treatment should be observed; all tension of parts ought to be relieved by deep, free incisions, which, by relaxing and draining the tissues, permit a better circulation; indeed, I have often arrested the rapid march of gangrene by such treatment. When a line of demarcation forms, which may occasionally happen, the question of amputation may arise. Occasionally the gangrene of diabetes is associated with most excruciating pain, not only in the affected limb, but apparently in the gangrenous parts. I have had two such cases, both females, and in each I performed nerve section, with partial relief in one, and with complete success in the other. In the first, I sectioned the posterior tibial, in the other the sciatic. The latter case I saw in consultation with the late Dr. L. M. Service, of Belmont, near the Falls of Schuylkill; the patient was 70 years of age, a large portion of the foot was already gangrenous, the pain in the foot and leg as far as the knee was excessive. I sectioned the sciatic in the middle of the thigh; the gangrene, which was not apparently hastened or influenced by the operation, very slowly extended for some weeks, until a point about four inches above the ankle was reached, where a line of demarcation formed. Subsequently, Dr. Service, Jr., removed all the gangrenous parts without encroaching upon the living tissues. The patient improved, was able to move about her room with comfort, and with entire freedom from pain; eight months afterward she died from an attack of acute dysentery.

DR. JOHN ASHURST, JR.: Of course, we have been familiar for years with the tendency of diabetes to suffer from gangrenous affections, such as carbuncle and, though not so characteristic, furuncle; and we have also known that intracranial injuries may give rise to diabetes, or rather to glycosuria. Verneuil considers the question of sugar in the urine from irritation of the floor of the fourth ventricle, and shows that it may be a temporary condition, the sugar disappearing as recovery from the injury takes place, and without leaving permanent results.

In many cases of diabetic gangrene, as Dr. Hunt points out, the quantity of sugar in the urine at different periods varies; it may, in fact, be absent at times, and thus even careful examination of the urine during such intervals may fail to reveal the condition. I have but one recorded instance of diabetic gangrene in my personal experience. The patient was a man of middle age, sent to the hospital with strangulated hernia of some four or five days' duration. The attending physician informed us that the man had long been a diabetic. Operation was deemed imperative, and was undertaken. There was but a small patch of gangrene in the bowel, which was left in the wound after relieving the constrict-

tion, so as to allow the formation of an artificial anus. Next day not only the bowel but the edges of the wound and the surrounding tissues were gangrenous, and death rapidly ensued. It was a case, then, of rapid moist gangrene, following a comparatively small incision. I have seen other cases, which I believe were instances of diabetic gangrene, though this was not demonstrated by an examination of the urine, that bear out Dr. Morton's statement of the liability for this condition to be precipitated by slight injuries, such as the rubbing of a boot or cutting a corn. The gangrene is moist rather than dry, which may be a valuable factor in diagnosis. Whenever we see spontaneous gangrene of the moist variety, it should at least excite the suspicion of diabetes.

There are, however, other influences which predispose to spontaneous gangrene, the most common, perhaps, being alcoholism. Verneuil refers to this fact, and says that in what he calls "alcohol-diabetes" gangrene is particularly apt to occur, as there are then two predisposing causes acting at the same time. Another cause of gangrene after amputations and other severe operation, as surgeons are aware, is the presence of certain forms of Bright's disease, the granular kidney especially. In these cases diabetes may sometimes co-exist, and the presence of sugar fail to be recognized, simply because it is not looked for.

As to the treatment of diabetic gangrene, locally, the less done, as a rule, the better. I would go further than Dr. Morton, and would wait not merely for the line of demarcation but for that of separation, which may appear some days, or even weeks, later than the former, before proceeding to amputate. In the majority of cases of spontaneous gangrene, diabetic or not, it is the better practice to trim away dead parts with forceps and scissors, rather than to attempt a radical operation. I have seen, after amputation, rapid return of the gangrene, spreading extensively and causing death. Constitutionally, it is a suggestive fact that the one remedy of greatest value in spontaneous gangrene of any kind is a remedy which has obtained a deserved reputation in the management of diabetes, *i.e.*, opium. Opium in doses of 1 grain, or 1½ grains, night and morning, or larger doses if needed, will often show its good effect in tending to arrest the gangrene in a short time. In many cases of spreading ulceration opium is also of value. For the treatment of diabetic gangrene then, opium internally and the less heroic treatment of the affected part seem to me to offer the best prospect.

DR. JAMES TYSON: Notwithstanding the exhibit made in the exhaustive paper of Dr. Hunt, I cannot but think that diabetic gangrene is a rare disease. Taking my own experience, re-

ferred to by Dr. Hunt, of fifty-five recorded cases in private practice since 1884, and probably at least twenty-five more prior to that date not so accurately recorded, and realizing, as I always have, its possible occurrence, the fact that not a single case has occurred under my observation is a significant one. It is to be remembered, of course, that many of these cases passed from my notice before they terminated. Dr. Hunt has asked for a parallel to his case of paralysis, etc. I cannot give an exact parallel, but one sufficiently so to justify an allusion in the same connection. A gentleman of multiplied business and financial interests came under my care for diabetes when he was 52 years old. Three years later there occurred a sudden hemiplegia. Within a few days after the paralysis occurred, the glycosuria disappeared and has not returned, though nearly two years have since elapsed. The percentage of sugar had been at one time as much as 7 per cent., and was constantly 2 or 3 per cent. In regard to the infrequency of diabetes among the poor no better proof could be given than the fact that in the Philadelphia Hospital, where more than a thousand patients are present at one time, it will often be impossible for weeks to get a case for lecture.

Dr. Morton has alluded to the extreme pain in diabetic gangrene. I have observed the same thing in gangrene associated with granular kidney. I scarcely think it should be regarded as peculiar to the gangrene of diabetes.

DR. JAMES DARRACH: I have seen but one case of gangrene associated with diabetes, the one noted by Dr. Hunt in his admirable and exhaustive paper delivered to the Society this evening. Two others of the legs and two of internal gangrene have also come under my notice in my practice. Those of the legs were in women over 70 years of age, and while I cannot recollect about the condition of the urine in these cases, from my custom of examining the urine in old people for sugar, it having been stated that it was not an unusual thing to find it in the urine of the aged, I doubt the probability of sugar escaping my notice. Dr. Hunt has mentioned that diabetes is a disease of the well-to-do, and referred to the rarity of the disease in hospital patients and among the poor. This would appear to be corroborated by the statement of Dr. Jordas, who writes that in an aggregate of 22,735 admissions into, I think, four hospitals in Lisbon, there was not one case of diabetes, and of 5,700 deaths, in 1862, four only were from this cause. Perhaps climate may, in a measure, account for this small proportion of diabetes, the inhabitants of southern countries being considered by some writers not so liable to this disease; and I might add that, as some mal-condition of the nervous system holds a prominent position in the etiology of diabetes, we might find an explanation in the fact that the inhabitants of

the sunny South are not exposed to the strain upon that part of their organization, as are those who live in countries where the brain is taxed to the utmost.

Dr. Hunt has spoken of the more palpable and well-recognized forms of gangrene. Dr. Wm. H. Dickinson has reported that in the autopsies of five cases of diabetes he has found peculiar morbid changes in the cerebro-spinal system, consisting in dilatation of the arteries and a degeneration of the nervous matter at certain points external to them, occasioning destruction and excavation of the tissue around the vessel. Kaposi describes a peculiar form of inflammatory gangrene of the skin, which I suggest might be owing—as has been described as the pathological condition in shingles—to necrosis of the terminal nerve filaments. I mention these as a probable addition to gangrenous affections in diabetes, which I believe Dr. Hunt does not refer to in his paper, and would suggest that the nervous system should be examined more than has been done in autopsies of this disease. I would inquire of Dr. Cohen whether he included in his statement cases with small amounts of sugar, and whether the sugar was established by the cupric oxide test alone. I feel interested, as from my own examinations I have been led to doubt the existence of this element in normal urine. The existence of sugar has been supposed from the reduction of the oxide of copper. This reaction is accounted for by the uric acid and kreatinin. I would like to ask Dr. Tyson how far his examinations sustain this view.

DR. W. OSLER: I think that Dr. Hunt has underrated the proportion of cases of diabetes that die with pulmonary complications. In my own experience of six autopsies there were three—two of consumption and one of gangrene. Freichs, in his important monograph, which contains a study of 400 cases, states that nearly one-half of all diabetics die of lung disease. There are three forms: The most common is a rapidly fatal lobar pneumonia, very liable to terminate in gangrene. Second is a broncho-pneumonia, which is still more liable to be complicated with gangrene. Thirdly, and most commonly, there is a genuine consumption, which is tuberculous, as demonstrated by the presence of the bacillus.

DR. NANCREDE: I would like to add another case to the list, which I had supposed was one of those referred to by Dr. Neilson, but it appears not; it was one of moist gangrene with large amounts of sugar in the urine, where the disease started in the fourth toe. In the other case, which Dr. Neilson mentioned to Dr. Hunt, I amputated the thigh high up for moist gangrene *not* due to diabetes. It illustrates the futility of amputating anywhere near the site of disease, for the artery was thrombosed to the groin. Unless the operation be done above the knee for gangrene of the

foot, we are almost certain to have recurrence in the wound with rapid spread of the disease and death. The practical outcome of this discussion should be to lay down a rule not to undertake any serious operation unless the urine has been tested for sugar, as well as for albumin. Since I assisted at an amputation of the breast in the practice of a friend, in which the urine had been found free from albumin prior to operation, but after the amputation the urine was found to be loaded with sugar, I have pursued this rule. Perhaps if the urinary examination included testing for sugar, as well as albumin, there would be fewer unexpectedly fatal terminations to operations and more cases of diabetes recognized.

DR. J. WILLIAM WHITE: If Dr. Hunt had been able to elicit from his correspondents the facts as to the coexistence or absence of certain other conditions likely to give rise to gangrene, we could better estimate the relative etiological importance of diabetes in these cases. Thus, in one of Dr. Agnew's cases which I had the opportunity of seeing, and upon whom I performed a knee-joint amputation, the subject was a man of 52 years, with chronic alcoholism and with marked atheromatous changes in the vessels. In this case we had, therefore, two conditions, either of which was competent to produce gangrene without the concurrent diabetes. Dr. Hunt's admirable and otherwise exhaustive paper would, perhaps, have been more conclusive had it been possible to include these points.

DR. S. SOLIS-COHEN: Dr. Nancrede's remarks suggest an explanation of the comparative meagreness of hospital records of diabetes, and of its supposed rarity among the poorer classes. Urinary analysis is not as general or as thorough as it ought to be. In the medical clinic of Jefferson Medical College Hospital, where it is the invariable rule to examine the urine of every patient, no matter how trifling the complaint, not a year passes that one or more cases of unsuspected diabetes, or at least glycosuria, are not discovered. Further, I would suggest that out-patient clinics or dispensaries, and not hospital wards, are the places to search for public records of diabetes of the poorer class. The Jefferson clinic has, I suppose, from five to ten or more cases of diabetes annually, in a service of about 4,000 new cases. At the Philadelphia Polyclinic, during nine months of this year, between 300 and 400 patients have been treated in the medical department, of whom three have been cases of diabetes. This large proportion is to be accounted for by the greater number of special clinics in the same building, reducing the attendance at the general clinic. Taking the entire non-surgical service of the institution, the proportion of diabetes would be reduced somewhat below that of the Jefferson clinic. Of course, in institutions like these, consultation cases increase the average of rare diseases of all kinds

above that of ordinary dispensaries. Still, considering the aggregate number of diabetics at these two clinics, of which I have personal knowledge, and remembering that urinary examinations are not as thorough as they should be in private practice among the poor, and that diabetics, as a rule, are walking cases until near the last; and, therefore, not to be looked for in hospital wards, I must doubt the force of Dr. Hunt's social distinction.

Dr. Cohen replied to Dr. Darrach that dependence was never placed upon a single test, and there was little probability that uric acid and kreatinine had been mistaken for sugar. One disadvantage of dispensary practice in these chronic cases was the inability to keep patients under observation for more than a short time. They wandered elsewhere, and might possibly be doubly or trebly reported.

DR. THOMAS S. K. MORTON: I should like to make more special point of what the practice of antisepsis enables the surgeon to accomplish in dealing not only with diabetes, but with all sorts and conditions of depraved system when upon them have been engrafted complications which, with modern methods of wound treatment, are at least entitled to have some attempt made for their relief. Under this heading would be included diabetes, Bright's disease, the graver infectious and contagious diseases, ataxia, and all other serious nutritional alterations dependent upon nerve or other change. Now the dangers principally to be dreaded in undertaking operations in persons subject to such diseases are those of *infection*. Little need be feared until this dire calamity has occurred. The most innocent forms of senile or other gangrene may at any time become so infected and change their nature to one of greatest malignancy. On the other hand, even large areas of necrotic tissue will not putrefy nor infect the system until bacterial decomposition takes place in them. I am convinced that infected gangrene existing without skin lesion usually has derived that complication from noxious bacteria lying deep in the various appendages of the skin. Hence the evident advisability of protecting a part about to become sphacelated by antiseptic covering; preferably by a carbolic or combined carbolic and sublimate dressing, for in such cases carbolic acid is a necessary constituent of the dressing that the fat and other skin glands may be deeply penetrated and disinfected by its influence—a property not possessed by sublimate and other disinfectants.

When infection takes place in a case of one of the above-mentioned diseases, the already depraved tissues are powerless to resist the onslaughts of bacteria, and frightful pillage and destruction are the result. Especially is the system unable to cope with the attacks of bacteria when diabetes is present, for then is provided in addi-

tion to the other favorite pabula of bacteria, glucose, which, in tissue solution, affords a most capital medium for the culture and dissemination of poisonous and tissue-destroying microorganisms.

We must then have ever in mind, that in dealing with surgical complications of any of the diseases which have been quoted, but more especially in the case of diabetes, that our object should be:

1. To prevent infection of a part about to become gangrenous, by instituting disinfection and subsequent protection; and, above and beyond all, never to apply a poultice.
2. Only to interfere surgically when absolutely necessary.
3. To operate only with thorough and powerful antisepsis—asepsis will never answer in these cases.
4. To relieve tension absolutely, and to eradicate as much of the diseased tissue as possible, and to disinfect thoroughly and render sterile all that cannot be so treated; for unless this be accomplished, a favorable result, or arrest of the destructive process, cannot be expected.
5. In suturing or dressing, to make no great traction upon any portion of the wound or its surroundings, and to provide most liberally for drainage.
6. To dress the wound in such a way as to prohibit subsequent infection, and to redress it upon the slightest indication.
7. To remember that non-union and non-healing will probably result, but that we may be bold in doing what seems indicated, for local harm cannot come save by infection.

DR. DE FOREST WILLARD: I cannot agree with the suggestion to make incisions to relieve the tension, I consider any interference injudicious in slow gangrene. The only safe plan is, to wait for the line of demarcation. Some months since, a man almost moribund came to the hospital with gangrene of the leg, and with crepitation extending as high as the hip-joint. Under excessive stimulation, twenty-four ounces of whiskey daily, he rallied, and I cut away the parts with scissors, through the knee-joint. A quick operation, or one near the part, would have caused death. Recovery has taken place, though a spot is now making its appearance on the toe of the remaining leg.

DR. TYSON: I am very glad to hear Dr. Darrach's remarks. I do not believe that sugar is ever present in normal urine. The copper-reducing substance in such supposed cases is most frequently uric acid.

DR. ASHURST: The pain of diabetic gangrene so frequently alluded to this evening is, I think, rather a feature of the local process than of constitutional cause. Slow gangrene, especially if being superficial, it involves a greater extent of nerve distribution, is more painful than rapid or deep-seated gangrene, where the nerves escape to a great extent, or are quickly destroyed. The recommendation to amputate at a very high point in cases of spontaneous gangrene, is by no means

new, having been strongly urged many years ago by James, of Exeter: it has been recently revived by Mr. Holmes and other surgeons, but the general consensus of surgical opinion is against it. In traumatic gangrene, of course, the case is different. There the proper course is, I think, to amputate as soon as possible, at a point well above the limit of the gangrenous portion.

MISCELLANEOUS.

GLANDERS AS AN INFECTIOUS DISEASE.—The following letter, upon the subject of glanders as an infectious disease, and the propriety of killing animals suffering from said disease or farcy, as soon as recognized, is published for the information and guidance of the Army:

BALTIMORE, JULY 24, 1888.

To the Quartermaster-General U. S. Army, Washington, D. C.

General:—In reply to your communication of July 16, I have the honor to submit the following statements and opinions:

Glanders is an infectious disease in which the infectious agent has been demonstrated to be a living micro-organism—a bacillus.

The bacillus of glanders was discovered by the German bacteriologists Löffler and Shutz, in 1882, and the discovery has since been confirmed by several other competent bacteriologists. It is found in the nasal secretions and ulcers of the mucous membrane, in the "farcy-buds" pustules and enlarged lymphatic glands of infected animals, and it is probable that it is also sometimes present in the urine.

It is a slender rod, somewhat similar in appearance to the well-known tubercle bacillus, but more uniform in size and somewhat broader. In preparations stained with fuchsin or with Löffler's solution of methylene blue, clear spaces are often seen in the rods which have been thought by some authors to be spores, but this is doubtful, as Löffler has found that no development occurs after the bacilli have been exposed to a temperature of 55° C. (131° F.) for ten minutes.

Pure cultures of this bacillus have been shown to produce typical glanders in horses and asses, and it is recognized by bacteriologists as the cause of the disease. The disease may also be transmitted by inoculation to guinea-pigs and to field-mice, which animals (preferably guinea-pigs) may be used as a test of the infectious character of the nasal secretions of a suspected animal.

Exact experiments have shown that the bacillus of glanders is killed by exposure for five minutes to a 5 per cent. solution of carbolic acid, or by a 1 to 5,000 solution of corrosive sublimate.

In practice it will be best to rely upon boiling water for the disinfection of all articles which can be immersed in it without injury—rope halters, blankets, curry-combs, bits, etc. To keep on the safe side, half an hour may be fixed as the standard time during which articles to be disinfected shall be immersed in boiling water, or exposed to steam at a temperature of 212° F.

Articles of leather should be repeatedly washed with a 5 per cent. solution of carbolic acid or a 1 to 1,000 solution of corrosive sublimate; or immersed in such a solution for at least one hour. If the solution can be used hot, say 180° F., without injury to the material, this will be desirable.

QUANTITATIVE ESTIMATION OF ALBUMIN IN THE URINE.—The possibility of estimating the amount of albumen in fluid by the difference in specific gravity before and after the coagulation of the albumin has been exper-

imentally investigated by Huppert and Zahor, and the last-named has attempted to apply the method to the urine. He recommends that the proportion of acetic acid required to coagulate the whole of the albumin be ascertained by a preliminary experiment. A specimen of the urine after filtration is then treated with the necessary amount of acetic acid and divided into two parts. One part is put into a bottle, which must be stoppered with an India-rubber cork, and kept in a water-bath at a temperature of 100° C. for ten minutes or a quarter of an hour. The urine is then cooled and filtered, care being taken to prevent loss by evaporation during this process. The filtrate and the portion of acidified urine originally reserved are then brought to the same temperature, in a water-bath, and the specific gravity of both very carefully taken. The difference between the two figures thus obtained, multiplied by 400, the average coefficient ascertained by experiment, gives the amount of albumin in grams, in 100 cubic centimetres. The average error is stated to be plus or minus 0.0175 gram, but may amount to 0.05.—*British Medical Journal*.

THE CASE OF DRS. MCCOY AND WILDMAN.—In the case of the revocation of the certificate of Dr. Henry G. Wildman, of Chicago, by the State Board of Health, and the action of the Governor in overruling the same, it is but just to say that in the McCoy case, upon which the decision of the Supreme Court was based,—holding that McCoy's certificate was not regularly revoked—McCoy virtually swore the Board out of court, swearing that he had not received notice to appear before the Board and had had no notice of the revocation of his certificate. At the time of the revocation of McCoy's certificate he was advertising himself to be at St. Louis, Belleville and Alton. The Board served notice upon a person who represented himself as McCoy, yet in court McCoy swore that he had never been in Alton. In a similar case against McCoy now pending in the Supreme Court the Board presented two witnesses, one from Belleville and one from Alton, who swore to having served notice upon McCoy to appear before the Board, also notice of revocation of his certificate. McCoy appeared in the first trial brought against him, but not in the second—he being rarely in Chicago. The action of the Governor is simply based on the decision of the Supreme Court in the first case against McCoy, and on technicalities. The Board will not let the matter rest where it is now.

GAME FOR INVALIDS.—After being properly prepared, boil a fine young bird until it is three parts cooked; then remove the skin, pick all the flesh from the bones, and pound it in a mortar, with a little of the liquid in which it was boiled, three tablespoonfuls of finely sifted bread crumbs, a teaspoonful of grated lemon rind, a sufficient seasoning of salt, and a grating of nutmeg. When pounded to a perfectly smooth paste, put the mixture into a saucepan with a little more of the liquid, and let it simmer gently for ten minutes. When finished, the panada should be slightly thicker than good cream. It will keep quite fresh and sweet for three or four days, and can be heated, a few spoonfuls at a time, and served poured over a slice of nice, crisp, hot toast, or in a very tiny dish with sippets of hot toast inserted round about. Nothing more quickly destroys the capricious appetite of an invalid than having a large dish of anything, no matter how dainty, set before them; they require to eat often, but only a very little at a time.—*St. James Gazette*.

HEALTH OF PITTSBURGH.—The report for November shows the number of deaths to have been 316, a rate of 16.5 per 1,000 inhabitants annually. Infectious diseases numbered 157, as follows: Forty-one cases and 21 deaths of diphtheria; scarlet fever, 57 cases and 5 deaths; typhoid fever, 59 cases and 19 deaths. In addition, consumption caused 25 deaths; diseases of the nervous system, 31; circulatory, 17; respiratory, 62; digestive, 13; violent causes, 33.

BROOKLYN MEDICAL AID SOCIETY.—James D. Conklin, manager of the Brooklyn Medical Aid Society has presented to the organization his first semi-annual report. The society was at first opposed by the Kings County Medical Society, but it afterward approved of its methods as a relief to people of the middle and poorer class, who, by this means, were enabled to secure medical attendance and prescriptions without the cost that usually attends such services. The society now has twenty physicians and sixty-six druggists who supply its subscribers free with attendance and medicine. The subscribers pay on the insurance plan: From 16 to 70 years at from 2 cents to 18 cents a week, rates being made for families. The report contains the following interesting facts in connection with this new society. The books of the Society were opened April 16, and 2,188 certificates of subscription have been granted since then, 619 being between 16 and 30 years, 125 between 30 and 60 years, 987 between 1 and 10 years, and 459 between 10 and 16 years. Certificate holders have made 867 calls on the society's physicians and the physicians have made over 900 calls on patients. There have been 978 prescriptions given to members and dispensed by the druggists, all of which service and medicine has been furnished to the certificate holders free of charge, in accordance with the rules of the society. Manager Conklin requests that the medical staff be increased to twenty-five and that the number of druggists be increased to 100, to meet the growing demands of the society. Out of the total number of certificate holders, only six have died since the formation of this society.

OPERATION FOR TORTICOLLIS.—Dr. Levrat has devised a new method of treating torticollis. Instead of operating subcutaneously, he cuts down upon the sternal tendon of the sterno-mastoid muscle, effected by a longitudinal incision 2 centimetres long. He clears the tendon with the forceps, passes a grooved director under it, and divides it. He then divides any tissue that may bind down the muscles at that spot, sutures the wound, and dresses it antiseptically with iodoform and gauze. Over the dressings he places the following: The head being enveloped in cotton wool, a silicated bandage is wound horizontally around it at the level of the forehead, and a similar bandage vertically over the crown and under the jaw. Where these bandages meet at the level of the mastoid process on the sound side, a small hook, with the concavity looking upwards, is inserted. Another silicated bandage is wound round the body below the axillæ, and through the thickness of the bandage a hook is inserted in the middle line in front, having its concavity looking downwards. When the bandages have dried, the two hooks are connected by a band of India-rubber, which assists the sterno-mastoid of the sound side to keep up a continuous traction and so correct the deformity. This apparatus and the dressings are left untouched for fifteen days, and the success of the operation is said to be assured.—*The Lancet*.

DANGER IN THE POSTAGE STAMP.—The *Sanitary News* calls attention to the fact that a postage stamp may in various ways convey contagion. One of the simplest and most plausible is that in which a postage stamp, partially attached to a letter to pay return postage, is sent by a person infected with some disease to another person. The disease is transferred in the first place to the adhesive stamp through the saliva, and in being attached to the letter by the receiver the poison may be transmitted to him in turn through the saliva. Another cause may be the infection of the stamp with disease germs. The stamp, having been exposed in a room where a diseased person lies, may become slightly moistened and thus retain the germ. That this is true can be proved very simply by a microscopical examination. We often see a person holding change for a moment in the month, probably not knowing that investigation has shown that disease germs can be carried by money. If one could see through what

hands the money has passed they would hesitate before using such a third hand. Silver money is as bad as paper money, but while many would hesitate to hold a dirty bank note in their mouth, they think that a silver piece, because bright, is apparently clean.

HEALTH OF CHICAGO.—November's mortality reports show that 1,061 people died in Chicago during the month; of these 298 died of zymotic diseases. Diphtheria caused 105 deaths during the month. Typhoid fever caused the death of 40 persons, and scarlet fever of 14. One hundred and seventy-nine persons died during November from constitutional diseases, 111 of these deaths being caused by consumption. From local diseases there were 445 deaths, 77 being from infantile convulsions. Diseases of development caused 65 deaths, and 73 were the result of violence, 18 being killed by trains.

THE RED CROSS SOCIETY OF FRANCE.—This Society, which rendered invaluable services during the Franco-German war, dispenses large sums every year for the relief of old and disabled soldiers and their widows and orphans. Last year it distributed to 1,760 soldiers who had been wounded in war, and 327 dependent relatives, a sum of 47,506 francs, as well as numerous artificial limbs and surgical appliances. The perfection of different types of ambulance wagons is a subject to which the Society is giving much attention.—*British Medical Journal*.

N. W. OHIO MEDICAL ASSOCIATION.—The thirty-second semi-annual meeting of the Northwestern Ohio Medical Association was held in Toledo on December 13, with a large representation from all over Northwestern Ohio. Dr. C. E. Beardsley, of Ottawa, was elected President for the ensuing year, Dr. F. W. Brayton, of Carey, first Vice-President, Dr. J. A. Duncan, of Toledo, second Vice-President, Dr. Durbin, of Woodville, Secretary, and Dr. Hathaway, of Toledo, Treasurer.

DISTILLERY FED CATTLE.—The health authorities have refused to allow the cattle ordered from the Chicago distilleries to be fed in Lake View.

Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department U. S. Army, from December 15, 1888, to December 21, 1888.

Lieut.-Col. Charles T. Alexander, Surgeon, and Capt. Henry S. Kilbourne, Asst. Surgeon, detailed for duty on Army Retiring Board, to meet at Vancouver Bks., W. T., at the call of the President thereof. Par. 22, S. O. 292, A. G. O., Washington, D. C., December 15, 1888.

By direction of the Secretary of War, First Lieut. Nathan S. Jarvis, Asst. Surgeon, is relieved from duty at Ft. Leavenworth, Kan., and will report to commanding officer, Ft. Lewis, Col., for duty. Par. 14, S. O. 290, A. G. O., Washington, December 13, 1888.

Capt. Louis A. La Garde, Asst. Surgeon, is granted leave of absence for one month, with permission to apply for an extension of three months. Par. 15, S. O. 290, A. G. O., Washington, December 13, 1888.

Capt. William E. Hopkins, Asst. Surgeon, is detailed as member of the Army Retiring Board to meet at San Francisco, Cal., vice Major Henry E. Tilton, Surgeon, relieved. Par. 3, S. O. 294, A. G. O., Washington, December 18, 1888.

Capt. William F. Carter, Asst. Surgeon, leave of absence granted in S. O. 116, Dept. of Texas, November 12, 1888, is extended five months, by direction of the Secretary of War. Par. 4, S. O. 292, A. G. O., Washington, December 15, 1888.

Capt. George McCreery, Asst. Surgeon, is granted leave of absence for one month. Par. 4, S. O. 265, Hdqrs. Div. of Atlantic, Governor's Island, N. Y., December 15, 1888.
